Collections can be seen as partially overlapping groups of texts, kept together by the relationships among themselves. In other words, we can imagine drawing a link between every pair of texts that appear in the same collection. This operation results in a network structure. Since network graphs are visual tools suitable for representing such kind of information, data was visualized into Gephi (Bastian, 2009) as an un-directional force layout graph, with nodes spatialized with a Fruchterman-Reingold (Fruchterman and Reingold, 1991) algorithm and sized according to their length. Nodes coordinates were subsequently extracted and used to produce the contour-plot model of RAWGraphs and the resulting SVG was reworked with a vector editing software to "reboot" the metaphor of the landscape.

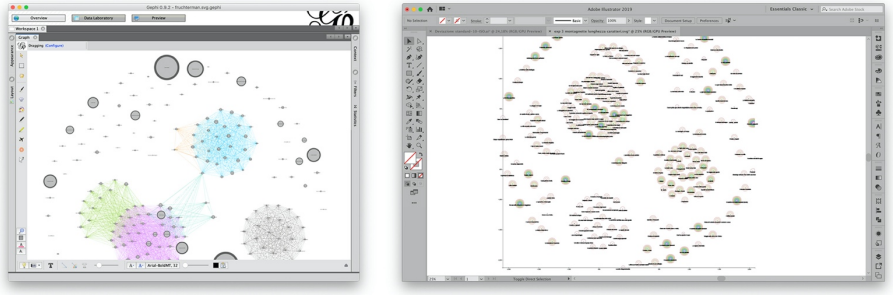

Figure 8. Gephi was used to position the texts in a space where the relationship between them and their chronology were significant (image on the left). Then, the coordinates of the nodes were used to produce the contour-tracing model and recreate the landscape metaphor (image on the right).

From this second result it is clearly visible the fact that writings could present very different behaviours and not all of them were published into collections. According to the visualised data, novels were all the time published independently and many stories were released only on magazines. Fruchterman-Reingold algorithm worked well for depicting that part of the territory occupied by connected elements: the closer they are in the space, the higher the number of connections they shared. However, the chronological dimension was almost completely unreadable, and the position of unconnected nodes is assigned randomly.

Again, reading the placement of texts through the metaphor of the natural landscape suggested the idea that some of their positions were meaningful, while others were inappropriate and needed to be fixed. A proper territory in fact, needs to present a morphology that could be read in a consistent way across all of its elements (Figure 9).

The metaphor, in fact, is capable of activating brain abilities of pattern recognition and spatial reasoning that are innate in humans; therefore, the reading of the visualization takes advantages of pre-attentive processing and ease the burden on attentional resources (Wise, 1995).

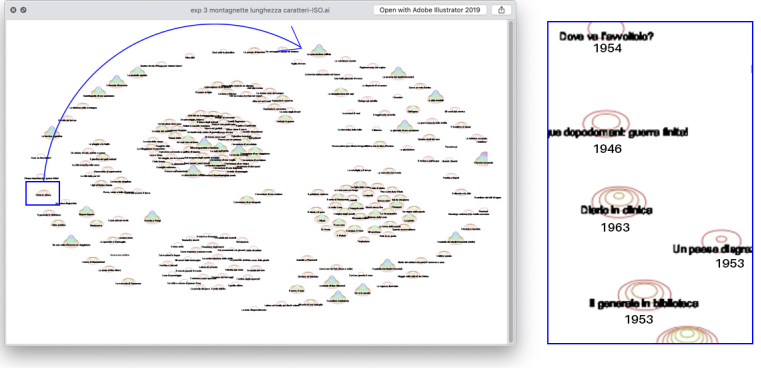

Figure 9. The computational position did not correctly represent all the nodes. In some cases, as shown in the image, the algorithm privileged the relation variable over the temporal variable or vice versa. The text "Diario in clinica" published in 1963 should be placed next to the other texts of the decade.

The position of those misplaced nodes needed to be modified, but it was not possible to identify any rigorous –or computational– method for doing so. For this reason, the team decided to adopt a solution based on a qualitative intervention on the visualisation: to touch-up the positions assigned by the spatialization algorithm, manually suggesting where elements should appear in the space (Figure 10).

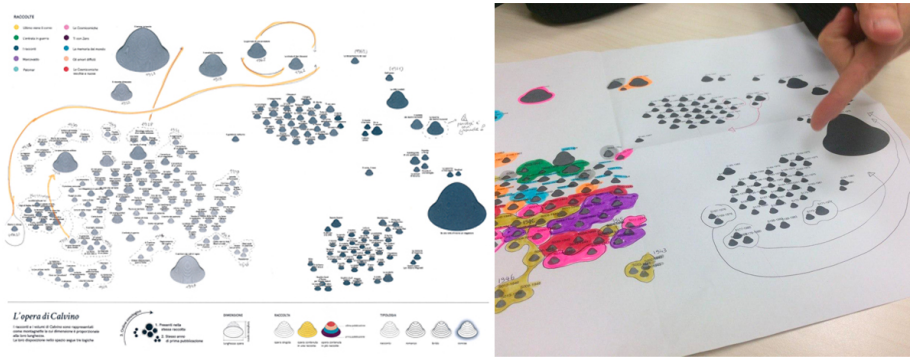

Figure 10. Many drafts were printed and manually annotated to decide how to fix anomalies in elements positions.

In an iterative sequence of transformations and evaluations, isolated nodes were grouped by years of first publication and successively scattered around the main islands of Calvino's collections, following a circular shape. Also, some nodes of the collections were at times repositioned, assigning a better position according to scholars' reflections on chronology and their reading of the territory. Position of nodes became relevant, allowing to read and understand the logic of this territory as a whole.

Nodes coordinates were once more retrieved from Gephi, but instead of using the contour-plot model of RAWGraphs, a custom interactive representation was produced using D3js (Bostock, 2011).

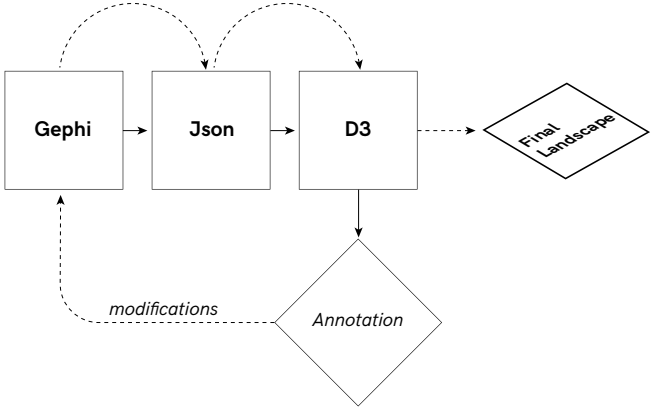

Figure 11. The iterative work of design, evaluation and adjustment of the nodes started with the use of network modelling tools (Gephi) to obtain the coordinates of the nodes (Json) and their visualization using the D3.js library. This computational process was evaluated by humanists, who modified the calculated positions of elements drawing from their knowledge.

After the review and annotation process, the process was repeated, altering the result according to the manual intervention.

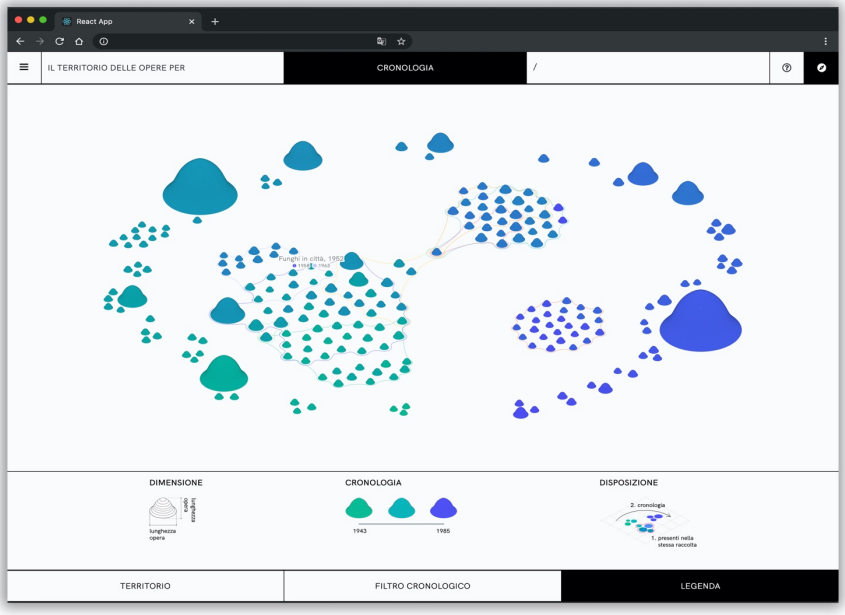

Figure 12. The final landscape is inserted in an interface that allows the exploration of the texts. In the image, the colouring of the "mountains" in the landscape represents the chronology from green (1943) to blue (1985).

3.4 Outcomes

The Archipelago of Calvino's Literary Works has been made available mainly in the form of an interactive webpage, with the possibility to search, filter, zoom and pan as if the visualization were a real interactive map of a territory[3].

Visualisation presents three islands surrounded by a big ring of smaller ones (Figure 12). Islands represent elements that are kept together by collections, whereas external ring is composed by the remaining written works, those that were not part of any collection. External elements have been manually scattered around according to first publication dates

[3] Find the visualization at: http://atlantecalvino.unige.ch/

and by following a clockwise direction that starts from the south of the Landscape (its central-bottom part).

For the elements part of the first island (the biggest, on the central-left portion of Figure 12), chronology had been partly sacrificed in favour of the grouping in collections. Still a general sense of time emerges from the artwork, because dates had been fuzzily taken into account in the manual orientation of collections and elements (Figure 13).

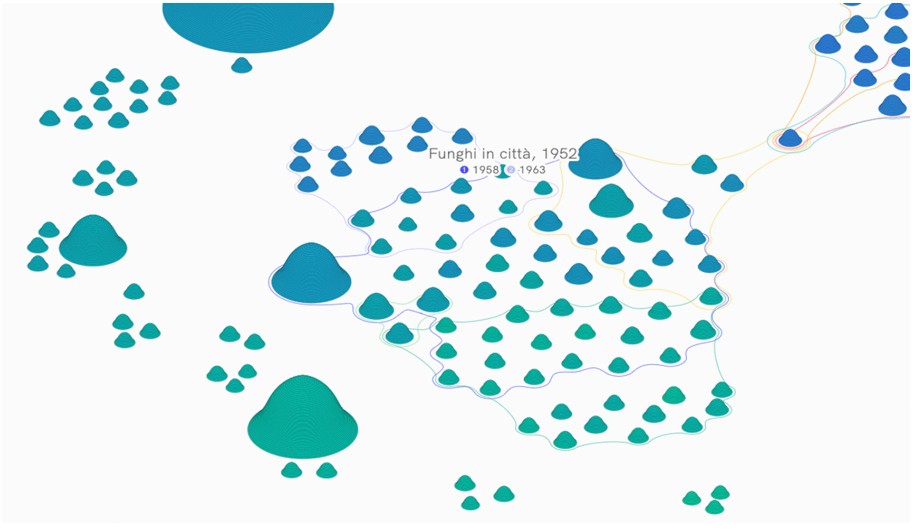

Figure 13. Detail of the first island: elements at the bottom are mainly green (older) than elements at the top, which are mainly blue (newer). Elements in the center are positioned according to a compromise between date and membership to collections. The position is the result of scholars' intervention.

The visualisation provides an immediate overview of all of Calvino's written works creating a nearly physical sensation of typologies and quantities. The diameters of collections oppose the elevation of novels, suggesting the idea that short stories are an important area covered by the author's production over his forty years long career.

The visualization also shows the multiple acts of re-mixing that the author performed on his own stories, together with the fact that earlier collections were less compact and more chaotic than the later ones. This is clue of the writer experience and awareness developed during the years.

4. Discussion

The process of creating literary critique is based on memory efforts and on scholar's capabilities of creating connections with culture and human history. The process of creating data visualization is usually based on quantifications and generative representations. This contribution reports on a viable way to integrate the two methodologies in order to design visual representations that are partly based on quantitative data and partly based on experts' elicited knowledge.

It is not unknown that that the realization of data visualization is a biased process (Kirk, 2016) which includes many choices that influence final outcomes. When creating the visualization discussed above, a key aspect had been to decide consciously on what to visualize among the many different data available and, once done that, to decide not to completely trust the result provided by the machine.

As described earlier, quantitative and comparable metrics were dropped in favour of the inconsistent and ill-defined information about collections. Although not an immediate decision, it is interesting to notice that this information is a direct result of Calvino's decision and presents an evident curatorial nature. Moreover, being so loose, it was the data dimension that less prevented scholars' tacit knowledge to emerge. The monographic setting in which this work had been carried out calls in fact for a deep understanding of the author's corpus through his personal history, his periods of break, his personal milestones, his professional achievements and the influence of external factors (like World War II and Partisan Resistance).

Some parts of that information could be derived, some others could be potentially embedded, but many others appeared as too complex to be fit into data. This explains the fact that metrics were too superficial to address needs of scholars, even if they perfectly fit the available tools for data visualization that are currently available.

This case study proves that visualization designers have to learn how to deal with ill-defined and incomplete information, even if it is hard to be exploited properly within data visualization tools. Precisely because of this fact, communication designers find themselves into an advantageous position if compared to other practitioners involved in data visualization, thanks to their expertise of manipulating graphics and images.

In the reported case, the use of a visual metaphor proved to be a particularly useful strategy, not only because it helped in the intuitive understanding of the visual outcomes, but mostly because it nurtured acts of speculation, pushing experts to ask the question: "where should this element be positioned to make sense within the context of this landscape?" For this reason, we can say that it represented an element of paramount importance in guiding the process of overcoming the limitations of tools for data visualization and for bringing the scholar within the loop of visualization.

The resulting visual artifacts are supposed to be a support for scholar's inquiry once completed. However, during their creation scholars actively engage with them, fostering the emergence of reflections, questions and eliciting their knowledge to emerge. For this reason, it is possible to say that visualization actively supported their process of critique, stimulating their work of memory and connection.

Nevertheless, they also show criticalities. This kind of visualizations require readers a lot of time to be digested, being so strongly customized and distant from ordinary visual models (e.g. bar charts or scatterplots). Some researchers pointed out that speed and efficiency better resonate with other fields of studies and that a visualization capable of slowing perception down is actually a *desiderata* in DH (Hinricks, 2018. Bradley, 2016).
To compensate, it is important to pay even more attention to the formal aspects of visualization, namely titles, legends, scales, etc. In addition, such visualizations may then require to be combined with a narration, in order to better explain the richness of the embedded information and to convey authors' aims and remarks.

5. Conclusion

Within this contribution we presented the outcome of an interdisciplinary work that brought together information visualization and literary studies for the making of an interactive data visualization designed in support to literary inquiry.

Creating this visualization has been of paramount importance to align habits and fashions of the two backgrounds involved, to develop shared sensibilities and eventually to start to understand how and at which extent it is possible to combine the work of critique with the work of creation of data visualizations.

The design process of this visualization pointed towards the overcoming of limitations of tools for data visualization. Such tools rarely allow for a complete exploitation of ill-defined and inconsistent information, which is however very common in the field of DH. The design process we presented, saw a methodological integration between methods of data visualization and design, with a particular use of the visual metaphor of the natural landscape deployed in order to elicit scholars' knowledge and bring them in the loop of visualization.

Similar methodological integrations, oriented towards the exploitation of inconsistent and ill-defined information, emerge as important contributions that designers can provide to those scholars that aim to create literary critique with the support of data visualization.

About the Authors:

Tommaso Elli is a PhD Student in Design at Politecnico di Milano and member of DensityDesign Lab. He is a communication designer and a creative coder specialized in information design and data visualization. His work is mainly conducted in the field of Digital Humanities.

María de los Ángeles Briones Rojas holds a Ph.D in Communication Design and is adjunct professor at the Politecnico di Milano. Member of DensityDesign Research Lab since 2015, her research is focussed on data activism and on the use of visualization to support the construction of alternative narratives.

Beatrice Gobbo is a PhD Student in Design at Politecnico di Milano and member of DensityDesign Lab. With her current research she is investigating on the role communication design and information visualisation in the field of explainable artificial intelligence.

Margherita Parigini specialises in Modern and Contemporary Italian Literature. In September 2017, she began her PhD on the author Italo Calvino. She is currently a Research and Teaching Assistant at the Italian section of the University of Geneva (CH).

Virginia Giustetto is a PhD Student at the Department of Romance Languages and Literature of the University of Geneva. She is specialised in Italian Literature, Philology and Linguistics. Her interests include Italian modern and contemporary literature and Digital Humanities.

Valeria Cavalloro is a post-doc at the Department of Romance Languages and Literatures of the University of Geneva. She is journal editor and author of books and articles. Her interests include theory of the novel, history of genres, Italian and Russian modern literature.

Michele Mauri is fixed-term research assistant at Politecnico di Milano. He teaches at the Faculty of Design in the Communication Design master degree. His research activities focus on information design and visual communication. Since 2019 he is scientific coordinator of DensityDesign Lab.

Acknowledgements: this research is conducted in the context of the project *Atlante Calvino: literature and visualization*. The project is funded by the Swiss National Science Foundation (SNSF) and it is led by Francesca Serra, Professor at University of Geneva.

Abstract | Patient autonomy indicators (PAI) template is a knowledge visualization tool for caregivers, aiming at supporting patient autonomy at the end of life by collecting and analysing patient data. We design PAI based on the Problem-Solving Cycle and the Event System Theory and iterate it through focus interviews. The writing of PAI is about a patient's story and shall be designed by three dimensions: narrative, numbers, and visualization. It involves collectivizing patient knowledge and provides a service-oriented process. In such a story, knowledge is the ability of terminal care services to impact patient autonomy. We conducted a PAI experiment with the support of four medical institutions in China. We concluded that PAI can help caregivers calculate and characterize patient knowledge, inspire their imagination and empathy, and perform suitable intervention activities for patients.

KEYWORDS | PATIENT AUTONOMY, PATIENT KNOWLEDGE, KNOWLEDGE VISUALIZATION, PATIENT SUPPORT

1. Introduction

Services in the modern world must receive and place thought and action in the center of their design (Secomandi, et al., 2011). Patient-centered services are essential to the doctor-patient interaction. In practice, people often adopt uniform service standards and ignore the assessment of patients' individual needs. The universally accepted ethical principle in the Western world is the promotion of patient autonomy. The concept of control related to autonomy affects a person's sense of dignity, helps reduce suffering, and improves the quality of life (Lavoie, et al., 2011). Therefore, the patient's beliefs and values serve as the basis for determining their needs and assessing the appropriateness of alternative interventions. However, autonomy is a multidimensional, plural, and multidisciplinary concept. It is important to analyze the characteristics of patient autonomy to guide the services. Patient autonomy analyses are currently supported with some scales, such as the Patient Autonomy Questionnaire (PAQ) and concise 4-item version (PAQs) (Vernooij-Dassen, et al., 2005). These tools require patients to have a clear awareness and relatively functional physical fitness to provide benefits. Many end-of-life patients are not in this condition. Some tools also assist in reflecting the autonomy of patients, such as France's national AGGIR, SMAF (Hébert, et al., 1988), and the ADL scale (Katz, et al., 1976) for supervising elderly customers. The Palliative Performance Scale version 2 (PPSv2) is most commonly used to predict the prognosis of patients and can estimate the workload. These tools are useful for fair medical resource allocation. However, changes in the disease lead to changes in the patient's ability to reason and move freely, i.e., fluctuations in their autonomic performance. How to evaluate and promote a patient's autonomy, especially for end-life patients, is still a challenging question.

We hypothesize that a close connection between patient autonomy and specific care practices will better guide autonomy support. This paper proposes an analysis framework, namely, the patient autonomy indicators (PAI) template, which is a tool for the caregiver (such as the doctors, nurses, social workers, service providers, etc.). It describes information in three dimensions event space-time, event strength, and patient condition, to analyse patient autonomy and design support strategies. PAI is a means to 'decentralize' knowledge resources and make patient knowledge easy to intervene by the caregiver. This template restricts the transformation of personal tacit knowledge into practically measurable and unambiguous operational understanding.

The PAI template has been tested in four medical institutions by six medical staff with more than ten years of medical experience. The results showed that the template can help improve autonomy support services more accurately, giving caregivers more confidence when facing end-of-life patients. The PAI template is flexible enough to handle different patient autonomy when used by care providers with different experiences. It can be used iteratively for better evaluations and strategies.

2. Beneficence and patient autonomy

The balancing of beneficence and patient autonomy is a critical issue in patient support because autonomous decisions are made intentionally and with a substantial understanding of and freedom from controlling influences. On the one hand, the highly technological nature of modern medicine and the patient's fear of erroneous decisions have strengthened the traditional paternalistic style of healthcare (Collopy, 1986). Illness deprives patients of their autonomy, and doctors define the patient's interests (Veatch, 1981). Therefore, it is hard to empower patients, and it is essential to emphasize the patient's agenda for patient empowerment, especially for dying patients.

On the other hand, calls for patient empowerment and autonomy in the sensitive context of palliative care may lead to an underestimation of the vulnerability of patients and increase conflicts surrounding care (Wilson, et al., 2014). The concept of autonomy support is sometimes misunderstood as to suggest that patients should be free to make their own medical decisions with little or no advice from providers. Van Eys (1991) states: "To be a patient is to be out of control. To be a patient is to be dependent. It is not the medical system that does that. It is the disease." Many patients, especially terminal patients, cannot cope with relatively complete independence and must rely on others (Ende, et al., 1989).

Solving this problem requires reasonable preparation or education of the caregiver. The caregiver is required to explain how to choose a service strategy based on the patient's wishes, knowledge, and understanding. Therefore, when and how to present and interpret a patient's knowledge is a significant challenge (Richards, et al., 2013). Caregivers should actively approach patients, understand their perspectives and feelings, and provide treatment and service options and relevant information when appropriate. Doctors in emergency care settings can quickly identify patient needs and reliably assess risks and benefits (Mc Cullough, et al., 1985). Palliative care faces more daily ethical issues and events (Christie, et al., 1986) that involve the patient's characteristics, such as personality, family, culture, and education. Patients in Asia have lower autonomy than patients in Europe and the United States (Mo, et al., 2012). Physicians traditionally discuss patient issues with the family rather than the patient because of the Confucian culture (Mo, et al., 2012). Palliative care is a new area in China, we need to pay more attention to the problem of patient autonomy. Although medical personnel can gain insight into the patient's world via instant imaginative identification behaviour, including the patient's unconscious motivation and attitude towards disease (Balint, 1955), the uncertainty of imagination (Scott, 1995) by caregivers can hardly lead to good results. Eppler & Burkhard (2004) defined

> "knowledge visualization aims to transfer insights, experiences, attitudes, values, expectations, perspectives, opinions and predictions, and this in a way that enables someone else to re-construct, remember and apply these insights correctly".

Therefore, we designed the PAI—a knowledge visualization tool to directly connect the vision of the caregiver with the problems or phenomena of patient care services. We use

narrative, visual, and number to present patient knowledge and promote the caregiver's reasonable moral imagination (Scott, 1997).

3. Design and experiment

3.1 Developing PAI

This section first describes the three stages of the design and implementation and then expands on the details of each stage.

Stage 1. Based on literature review and field surveys, we developed a prototype of the patient autonomy indicators using a problem-solving cycle (Sternberg, et al., 1986) and event system theory (Morgeson, et al., 2015).

Stage 2. We organized a group discussion to iterate the prototype for improvements.

Stage 3. We designed and conducted experiments that required participants to use the PAI for one month in a real context. The participants were interviewed for their feedback.

The design of PAI started with our two-month field surveys in the Affiliated Hospital of Jiangsu University. We want to investigate how doctors and nurses can help end-of-life patients improve their quality of life. And we found two problems: First, the patients at the end of life are weak and have difficulty withstanding the routine consultation survey, but we still need to get information about patient needs. Second, some tools or scales completed by the caregivers measured patient autonomy, but they were less relevant to clinical practice. Patient autonomy fluctuates with the disease, and we must analyse specific issues. Therefore, our hypothesis is that patient autonomy is closely related to a particular reality, which may reasonably solve the problem of supporting patient autonomy. Therefore, we performed an exploratory study. Theory-based exploratory research helps ensure content validity in the scales (Hinkin, 1998). We considered that the differences between the patient's personality and the subjective evaluation of the caregiver may require iteration of the solution. We constructed the framework of the prototype with the theory of the problem-solving cycle (Sternberg, et al, 1986) that includes the steps below:

- Recognize or identify the problem;
- Define and represent the problem mentally;
- Develop a solution strategy;
- Organize knowledge about the problem;
- Allocate mental and physical resources for solving the problem;
- Monitor his or her progress towards the goal;
- Evaluate the solution for accuracy.

"The cycle is descriptive and does not imply that all problem-solving proceeds sequentially through all stages in this order" (Pretz, et al., 2003). We can use the steps of problem-solving cycle flexibly and we designed PAI usage steps based on the steps above as below:

- Identify and represent the problem or phenomenon (Problems encountered during patient care);
- Solution strategy (Ways of solving the problem);
- Organize knowledge (Organize patient knowledge from three dimensions: time and space, event intensity and patient condition);
- Measure (Six operational definitions for the above three dimensions);
- Score (Statistics on the allocate section);
- Patient autonomy support strategy (Designing action strategies that support autonomy based on 'solution strategies');
- Feedback (Caregiver describes patient's response after experiencing supportive autonomy strategies);
- Evaluation (Caregiver's evaluation of patient autonomy support strategy based on feedback).

We used the event system theory (Morgeson, et al., 2015) to divide the section of organizing knowledge, which helps provide a meaningful description of the development process of events. "The event system is a complex of three interacting event components, including event strength, event space, and event time" (Morgeson, et al., 2015). We divided knowledge sources according to the three components and added patient condition items to organize patient knowledge more comprehensively. We set specific secondary indicators for the measure section (Figure 1) and use a 5-level Likert scale to measure the details of problems or phenomena. The design prototype (Figure 1) shows that the first row is primarily the necessary information of the patient and the caregiver. The steps are in order from left to right in Figure 1.

Figure 1. Patient autonomy indicators (PAI) prototype.

3.2 Iterating the PAI prototype

To improve the PAI, we cooperated with the training group from QELCA (Quality End-of-Life Care for All), Jiangsu China. Eight palliative medical staff were invited in a 2-hour focus interview on this prototype (Figure 2). They are two doctors, four nurses, and two social workers.

Figure 2. Palliative medical staff participate in the interview of PAI prototype iterations.

The views and opinions collected included three aspects. The first step was to make the concepts and category relationships clearer in the PAI, such as, “Many concepts in the table, and it is a little hard to distinguish the relationships.” And “I need time to understand these categories and their meanings.” The second step was to simplify the quantitative calculation part of the PAI to make it easier to operate, for example, “I think I have no time to calculate the ‘score’ section by myself because I am busy” and “What is the familiar standard code that can be used as a reference in the ‘measure’ section?” The third step was related to patient privacy: “We write some details of patient life that they may mind being seen by others.” From then on, we iterated the scale (Figure 3) to optimize the visualization using a gradient ramp to guide the fill level from left to right, from objective observation to subjective evaluation.

Name:	Gender:	Age:	NO.	Doctor&Nurse:			Score	Evaluator:	Date:
Identify and represent the problem or phenomenon	Organize knowledge	Measure	Weak←--------Autonomy--------→Strong (1----------2----------3)					Patient autonomy support strategy	
	Space & Time	Space	Indoor		Area		Bed/Chair		
		Time	Min		Hour		Day		
	Event strength	Degree	Weak		Moderate		Strong		
Solution strategy		Scope	Point		Part		Body	Feedback	Evaluation
	Patient condition	Expression	Invalid		Fuzzy		Clear		
		Disability	Severe		Moderate		Mild		

Figure 3. Patient autonomy indicators (PAI) template.

The quantization part was simplified into three increasing levels with the vocabulary familiar (such as indoor, area, bed/chair, min, hour, etc.) to the caregivers, which made it easier to judge. We emphasize that people who use PAI should keep it properly. We also deepened the color saturation of the design of the patient information portion, which increased the difficulty of reading the information (Figure 3) to reduce the possibility of patient information leakage. In the 'score' section, it is a simple measure to make statistics on the degree of indicators and create an overall impression of patient autonomy. According to the focus interview, we also map out the scoring indicators for 'score' section (Table 1)

Table 1. Patient autonomy scoring indicators. (A score below 6 is invalid)

Score	Autonomy level	Support strategy
6—10	Weak	The caregivers should establish a smooth communication channel with the patients' agents, such as family members.
11—14	Moderate	The caregivers should make supportive behaviours and cooperate with patients' agents to support patient autonomy.
15—18	Strong	The caregivers should develop patient autonomy individually or in collaboration with stakeholders.

Caregivers can use it to determine the extent and frequency of supportive behaviors, such as attention to needs, empathy, care, recognition of individuality, information provision and dignity (Dickert, et al., 2009) to respect the patient's autonomy. The use of these indicators is elastic, and we cite similar cases in the experimental section according to the principles of indicators to provide a reference for the participants. Overall, the higher the patient's autonomy, the more comprehensive and supportive behavior is required. Caregivers received patient's feedback after service and evaluated the effects of describing and supporting the patient's autonomy.

The PAI is a complex form of reporting that combines narrative, numbers, and visualization. It uses the three dimensions to organize the patient impression. First, PAI has some form of knowledge 'narrative'—a scenario, a storyline of patient knowledge, and a storyline of how problems arise. Knowledge narrative focuses on how patient knowledge resources interact and enable caregivers to intervene. Second, PAI identifies a set of challenges for patient knowledge analysis and caregivers' efforts to support patient autonomy. A patient's story includes a knowledge narrative (the section to 'Identify and represent the problem or phenomenon') and a statement that supports autonomy (the section to 'Patient autonomy support strategy'). It aims to enhance attention to the details of care services.

The PAI also suggests that ‘numbers’ can be attached to challenge analysis to show how they are implemented, that numbers correspond to different concepts and hierarchies and that they show the authenticity of the proposed problem analysis challenges to allow the knowledge narrative to flourish. With the ‘organize knowledge’ and ‘measure’ sections the numbers can be used to explain part of the story. The caregivers can fill in the blanks numbers to support narrative or only tick the blanks to determine the degree of autonomy as shown in Figure 4, which makes the analysis and evaluation possible.

Name: XXX	Gender: Man	Age: 68	NO. X	Doctor&Nurse: XXX XXX					Score	Evaluator: XX	Date:13.11
Identify and represent the problem or phenomenon	Organize knowledge	Measure	Weak←--------Autonomy--------→Strong (1----------2----------3)						13	Patient autonomy support strategy	
The patient with reduced mobility went to the toilet at night and did not call a family member to help. There is a risk of falling. (The bathroom is 3 meters from the bed. It takes 15 minutes to complete the toilet process. The patient is frail with NRS Grade 3 pain, especially when moving .)	Space & Time	Space	Indoor		Area	3m	Bed/chair		3	Moderate autonomy: 1. Listen to the patient's reasons for not wanting to wake up the family; 2. Explain the risk of falling; 3. Family members express their support; 4. Moving beds; 5. Ask the patient his feeling after bed moved and encourage him and his family members.	
		Time	Min	15	Hour		Day				
	Event strength	Degree	Weak		Moderate	3grad pain (NRS)	Strong		5		
Solution strategy		Scope	Point		Part		Body	√		Feedback	Evaluation
We are going to lean the bed against the wall and the other side against the family's bed to prevent the patient from getting up at night without anyone knowing.	Patient condition	Expression	Invalid		Fuzzy		Clear	√	5	Patients' families accept this arrangement to avoid the risk of falling patients.	Good support for patient autonomy. The patient can safely rely on his family.
		Disability	Severe		Moderate	√	Mild				

Figure 4. An anonymous patient case. Caregivers can fill in PAI with reference to other scale data. Such as pain measurement—Numerical Rating Scale (NRS) in this case.

The PAI allows visualization to function in place of a written story (Segel, et al., 2010), and it’s not only an information analysis tool but also, above all, a data collection tool first. It implies a combination of evidence-based medicine and narrative medicine. The overall visualization of patient autonomy, including narrative and numbers, forms a network – the final report. These figures show that caregivers are serious about their patients and can be held accountable for their actions and desire to support them. Visualization constructs a certain “wholeness” in the organization of numbers, while the narrative suggests how the legitimacy of the patient autonomy strategy is formed. The PAI focuses on descriptive data and knowledge generation interventions, not knowledge application interventions. It aims to address clinical issues in medical and nonmedical settings and to support patient autonomy in the context of daily care.

3.3 Experiment

We performed an experiment in China. It was an exploratory study with small samples, and qualitative research methods were used. We recruited 6 participants from the palliative

caregivers, aged 32-46 years and were from four medical institutions (Affiliated Hospital of Jiangsu University, Zhenjiang First people's Hospital, Dongwu Hospital and the third people's Hospital of Zhenjiang) in Zhenjiang, China.

We first showed a 30-minute video to the participants, explaining the content of the PAI and the filling process. The participants tried out the PAI template for 20 minutes as a training exercise. All the participants were able to finish the exercise in time, showing that they will be able to use it for analysis and decision-making in the real environment (Figure 5). The participants then used the PAI template for one-month for the end-of-life patient care, after which the completed PAI's were collected. Each participant was asked to submit 4-8 completed PAI's and invited for a semi-structured interview to discuss their feelings, recommendations, and related experience. The interviews were recorded as qualitative data.

Figure 5. Palliative caregivers work in the real environment.

4. Results

This session describes the qualitative results from the semi-structured interview at the end of the study. Descriptive conversations about the use of PAI template, and reflections that have been recorded, transcribed and marked as discrete categories using content analysis methods (Bryman, 2016). Thirty PAI templates were returned, and twenty-eight were valid. Two templates were invalid due to incompletion because of the patient's death. We performed semi-structured 30-60-minute interviews with 6 participants.

There are three observations from the interview recordings. The first point is the use process of PAI, such as "I was not familiar at first but got quickly to do it, and it was convenient", "I think the tool is useful", "I will put it together with the patient medical records for reference", "It is a bit inaccurate when used for unfamiliar patients, but re-evaluating can make me think more." The second point is about reflection on their work. For example, "It reminds me of more about nursing, and maybe there are other ways of care I could provide for the patients to choose from.", "I can understand and comfort him", "I found that I could

do something more for him instead of walking away after nursing", "I began to think about when it was more appropriate to provide care for him". And there are some emotional expressions included "I think I can understand his pain and be prepared to say something to comfort him", "I think I should get his consent before I help him, and he will feel better", "I found that by carefully explaining the details of the care, he was more cooperative and thankful, and we were easier for each other", "I used to keep some questions to myself, but now I can write them down." The third point was the recognition of the differences. The participants realized that solving problems was not the same as supporting autonomy, "I think I cannot cure him, but I can comfort him", "This is a difficult problem, I cannot think of a right way, but I listened to the patient for a long time and it seemed to help".

The participants found the visual design of the PAI template to be intuitive, it helps to reduce the cognitive burden of processing information. It is important in this template to distinguish the problem-solving strategy from the strategy that supporting autonomy. We may not solve all the problems, but we can still support autonomy. It can help the caregivers to describe the problems in detail and increasing empathy.

5. Discussion

The present study found that PAI achieved the goal of supporting patient autonomy in daily care. In any doctor-patient relationship, there is an area of shared knowledge related to daily tasks that are important to support patient autonomy. Health care professionals "shared humanity" (Taylor, 1994) to understand patients is not a secure or stable knowledge. Imagination is inspiring for caregivers, helping them to think more about daily details for deeper their understanding and helping facilitate doctor-patient communication. PAI enhances the explanatory power and makes the intervention of problems or phenomena easier.

The evaluation in the PAI template is an estimation of the patient's autonomy. It can be repeatedly used for analyzing particular problems. And we should use it with the conventional elderly assessment scale and other autonomy measures such as PAQ, ADL, and PPSv2, etc. The PAI template can be digitized so that it can be integrated into medical systems to facilitate the management of the patient's knowledge. We could also adapt the PAI for patients with other disabilities such as pediatric patients.

PAI can help balance the beneficence and patient autonomy, which is essential for supporting patient autonomy. Acting beneficence is more complicated than just doing what the patient wants to do. PAI allows the perception of nonverbal cues (Scott, 1997) and pays full attention to the patient. It can suggest the timing and method of serving patients in considering the actual situation. In western countries, people tend to send elderly patients to nursing centers, while in China, patients are usually cared for by family members. The

culture of care is different. As our participants are all Chinese, PAI needs to be further tested in a different cultural context.

6. Conclusion

The PAI presented in this paper converts specific problems and event elements into patient autonomy knowledge. The patient real-life narrative becomes the core for analysing their autonomy, which leads to more appropriate and relevant intervention recommendations. According to the qualitative evaluations, the PAI can trigger the imagination and empathy of the caregiver and made them correct details of their work. Insight into the details of the problem helps caregivers understand the knowledge of the patient's condition and feelings. The PAI template provides a visualization tool for supporting patient autonomy, which is essential for patient-centred palliative medical services. As we know that cultural differences have a great impact on patient care, we will expand the scope of caregivers and explore the effect of PAI on patient autonomy support in different cultural environments in the future.

Performativity as a language of sense-making for cultural service design in local museums

Shu Hongming*[a], Eleonora Lupo [b],

Abstract | The local museum in the future will not only be a space to display the local culture and history, but also strive to serve as a shared place connects communities and their memories. As a promising channel for social cohesion, cultural services in museums create value through triggering social dialogue, open participation, as well as fostering relationship-building and leading users' sense-making. To create immersive experiences where visitors are both audience and performer, performance theory was introduced in this research to propose the concept of "performative cultural service". This paper, after a comprehensive review of performance studies, summarizes the performative strategies for sense-making as well as its mechanism of creating impact, to explore the possibility of achieving performativity in cultural service design. After a comparative analysis on the structure of service and performance, this research presents an initial design framework and corresponding design strategies in the context of the local museum.

KEYWORDS | PERFORMATIVE CULTURAL SERVICE, SERVICE DESIGN, LOCAL MUSEUM, SENSE-MAKING, PERFORMATIVITY, CULTURAL SERVICE, SOCIAL COHESION

1. Introduction

Nowadays, museums are shifting from a site of authority to a site of mutuality to respond to challenges posed by postmodernism and post-colonialism, through becoming more democratic and inclusive of contemporary social diversity (Soares et al., 2018; Hooper-Greenhill, 2000). Museums take toward issues of democracy and empowerment through redefining the relationship with their audiences and presenting both side opinions and interpretations (Hooper-Greenhill 2000; Wood 2010). In this context, the local museum is playing a pivotal role in connecting the community around them, not only as a carrier of shared memory, but also as a shared space for the exercise of community power(Ocampo & Lersch 2013).

As the overall social change and, therefore, the imperative in creating new opportunities for community engagement (Wood, 2010), museums social responsibilities are underlined (Sandell, 2003). Museum phenomenon, which must also be understood as a process, phenomenon, flow, or event (Scheiner, 2017), should control the representation of a community and its highest values and truths (Duncan, 1995). Different from the traditional museum, where is never the direct expression of life or reality itself and where the visitor is never in a relationship of direct and unmediated contact with the selected material artifact, Ocampo and Lersch (2013) argued that the community museums imply creativity. Visitors may not accept given solutions, but instead seeks to invent new ways of addressing challenges. Thus, the local museum could serve as a tool for constructing collective subjects to build a joint interpretation of their reality and their history for the generation of awareness.

Cultural services are sense-making activities that allow for open participation, dialogue triggering, and relationship building, which could be a strategic approach in leading and fostering social cohesion and museum inclusion(Shu& Lupo, 2020). The strategic importance that these services, for strengthening the cultural heritage enhancement actions, has long been the focus of the Italian Ministry's attention, according to guidelines issued in 2009 on the activation and assignment of services to the public in Italian cultural institutes (circular + annex of the General Secretariat No. 49 of March 23, 2009). Cultural services, as foreseen by the art. 115 of the Code, can be managed directly or indirectly. The General Direction for the Promotion of Cultural Heritage also provides for the preparation of tender bids to be used by the peripheral Institutes of the Ministry, when a tender procedure must be issued for the management of services to the public in concession to third parties.

Services have been widely associated with theatre and experience economy, that every business is seen as a stage with scripts, front-end service personnel as actors, and service encounter as a performance (Grove& Fisk,1992). Pine and Gillmore (1999) argue that staged experiences fulfill a larger subset of customer needs, therefore valued higher by customers than manufactured goods or extracted raw materials. Rifkin (Rifkin 2001) further argues that culture itself is being pulled into the commercial sphere in this experience economy. Many

cultural undertakings are dedicated to the creation and reproduction of certain special psychological experiences (Toffler,1970), that in almost all developed high-tech societies, the art-based 'experience industry' is undergoing significant development for mass entertainment, education, etc.

As an interactive and intuitive language, performance could coordinate all the elements systematically, from the physical environment to human senses, from the narrative to emotional resonance, to achieve an optimized and impactive experience. In this paper, performativity is introduced as a sensitive language to design cultural service experiences in museums. After a comprehensive review of performance and its mechanism in sense-making and impact-creating, this research explores the possibility of achieving performativity in cultural service design. This research presents an initial design framework and corresponding design strategies in the local museum's context through analyzing cases. All these results have been tested in a design workshop for the Wuxi Museum at Jiangnan University, 2020.

2. The mechanism of performance in sense-making and impact-creating

Sense-making, as defined by Kolko(2010), is “an action-oriented process that people automatically go through in order to integrate experiences into their understanding of the world around them”. It is an active concept, as meaning generates from social interaction and enactive experience that matter to the subject (Jaegher& Paolo,2007) . As Freire(1982) states that, man is a subject because he is a being of relations, capable of reflection, of critical thought, of historical awareness; a being who can choose, create and transform reality; a being cannot renounce without becoming a mere spectator of event, a passive receptor, an object. While performativity could be shared language for participation, presenting and representation, demonstration, and even for prototyping or negotiation.

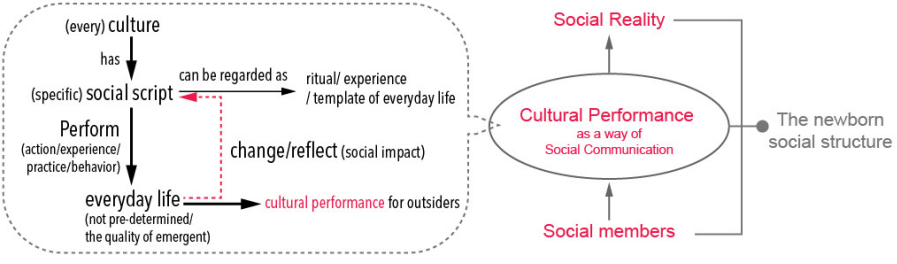

Figure 1. Cultural performance and its function on social communication imply its potential in enhancing public participation during positive social change.

In *The presentation of self in everyday life*, Goffman(1978) metaphorized everyday life behavior into the performance that people present themselves to leave a desired impression on others. Even people follow culturally specified social scripts, according to Bauman(Bauman 1984), performance has a quality of reflexivity in the social-psychological sense, as it can provide a situation that enables one to enter the other's attitude and experience and start to look at itself from other's perspective. By raising the level of consciousness, cultural performance with reflexivity could facilitate social identity achievement in any social context. Furthermore, social reality can be constructed and communicated among social members through social communication (Phillipson, 1972), from which interactive and resilient social structures are born out(Singer, 1955). Therefore, cultural performance and its social functions imply its potential in enhancing public participation during positive social change (Figure 1).

One of the most basic common characteristics among cultural performance is what was called" the shift in the frame of experience"(Bauman, 1984). We could transform ordinary or extraordinary experiences into meaningful signs and messages, through which groups can stage, display, and explain social experiences (Bakhtin 1968). However, as stated by Colebrook(2002), art may well have meanings or messages, but what makes it art is not content but its affect, the sensible force or style through which it produces content. While affect is a sensation produced in an encounter between body and event, and refers to emotional, often automatic, embodied responses that occur in relation to something else – be it object of observation, recall of a memory or practical activity(Thrift, 2007). Connect with visual art, Bennett (2005) argues that affect produces real-time somatic experience outside the frame of representation, but a diversity of encounters, processes and experiences that extend the relationships over time and in different, frequently unusual spaces. Affect, for Kim and Bianco (2007), is connected both to a capacity for action and to a sense of aliveness, where it is that vitality that prompts a person's desire to connect and engage (perhaps with others or ideas). Jaegher and Paolo(2007) defined participatory sense-making as:

> "the coordination of intentional activity in interaction, whereby individual sense-making processes are affected, and new domains of social sense-making can be generated that were not available to each individual on her own." (Jaegher& Paolo, 2007, p.497)

In this definition, it is indicated that what undermines the sense-making is not the lack of expressiveness, but the ongoing engagement that has been unhinged. So she introduced the concept "coordination", like patterned behaviour such as synchronization, mirroring, anticipation, imitation, to connect temporal aspects of interaction and their consequences for joint and individual sense-making. Meanwhile, in *The Structure and Deconstruction of Drama*, Sun(2016) proposed five types of aesthetic psychology that could improve sense-making and impact-creating with audiences' participation, that is Internal imitation, empathy, aesthetic distance, users' imagination and creation, Psychological time and space.

While critically viewed through the lens of design, sense-making is a motivated, continuous effort to understand connections, in order to anticipate users' trajectories and act effectively. (Klein et al., 2006). If people behave according to social scripts, we may succeed in codifying the environment(Van Doorn, 2007) or services to support visitors in carrying out these scripts and performing their daily life, or to lead them to a more extraordinary performative experience.

3. Performativity in cultural service

Performativity is a language which functions as a form of social action and has the effect of change(Cavanaugh 2015). The concept was first defined by philosopher of language John L. Austin(1975) as the capacity of speech and communication to act or to consummate an action.

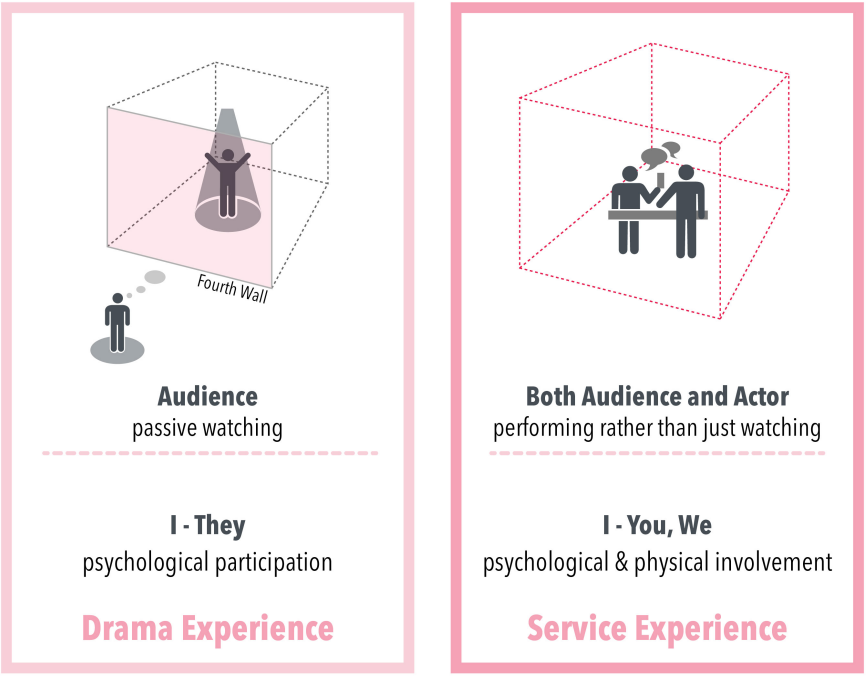

Figure 2. The theatre and the service represent two different modes of space and dynamics in the experience industry.

Performativity works through cultivating or guide the subject's sensitive richness, which includes not only the five senses like eyes, but also the so-called spiritual senses, practical senses and the senses of humanity (Sun 2016).If regard cultural services in museum as sense-making activities, performativity is to magnify the sensitivity of visitors to understand through interactive narratives, or to make visitors a witness to the historical process, or to encounter themselves through being one part of the story.

Service and performance are closely linked, and services themselves have been widely described as "performances". The metaphor that behavior is drama(Grove& Fisk,1992) engenders a framework for describing, understanding, and communicating about services experiences(e.g. rehearsal, scripts and routines, backstage, costuming, etc.) However, the theater and the service represent two different spatial and dynamic modes in the experience industry (Figure 2). The theater space is divided strictly into two parts, that actors perform on the stage while audiences sit quietly in the auditorium. While, many services' environment is more inclusive, where service providers and users could interact with each other. The difference between theater and service is whether there is a "fourth wall" (Sun 2006), an invisible wall of a set through which the audience sees the play's action. Thus, besides the psychological participation in drama, users in a service could also conduct physical involvement in a realistic environment by reacting, responding, and co-creating to change or influence the experience.

Figure 3. Dialogue in the Dark provides immersive experiences where visitors are guided by blind guides in absolute darkness.

For example, Dialogue in the Dark (Figure 3) is one of the world's most exciting life-changing experiences, where blind guides guide visitors in absolute darkness. Visitors are pushed out of their comfort zone into a world without pictures to experience daily life environments like enjoying a walk in the park, taking a boat cruise, or visiting a café in specially designed darkened rooms. A role reversal is created in these experiences whereby the sighted becomes blind, and the blind gain sight. Thus, Dialogue in the Dark could provoke empathy and advance social inclusion to the blind.

As a language for communication, exploration, and prototyping, performativity could also enhance collective sensitivity by valuing each participant's creativity and imagination. For example, 100 in 1 day is a creative activity initiated in major cities worldwide, encouraging people to spend 100 days thinking about the social problems around them, and perform their solutions together on the same day, to trigger social dialogue. Figure 4 shows the practices in Hongkong, 2016. A residents' innovative actions against the prohibition of bicycles on roads have triggered the public's reflection on the question of "who should be the user of roads."

Figure 4. A residents' innovative actions against the prohibition of bicycles on roads in Hongkong, 2016 have triggered the public's reflection on the question of "who should be the user of roads."

In a series of exhibitions Sensitive Environment designed by Studio Azzurro, different languages and digital narratives are integrated to involve the viewer in a story of images and sensations. Stories will be activated and "live" again when visitors get in touch with the characters on the screen, making himself the bearer of that story and its message. In this case, the viewers' interaction is an indispensable component for this artwork, and the viewer will activate his or her own as an echo through the encounter. Visitors' interactions are combined with digital content to achieve multiple narratives, associations, and meanings.

4. Design strategies for performative cultural service for local museum

Performative cultural service doesn't change social reality directly but isolates a space (situated context) for visitors to encounter, involve, explore, negotiate, collaborate, or even try an alternative(engaging in a process). After that, visitors back to the reality may gain a new perspective or inspirations to reflect society reality (echo) and be proactive for potential social change. The performative experience is co-created, where designers create a context to support visitors' own sense-making and provide different storylines or possibilities for visitors to explore, while visitors interact with narrative to create their personal experience and story. Therefore, we could divide performative cultural service experience into three stages: Context, Process and Echo (Figure 5).

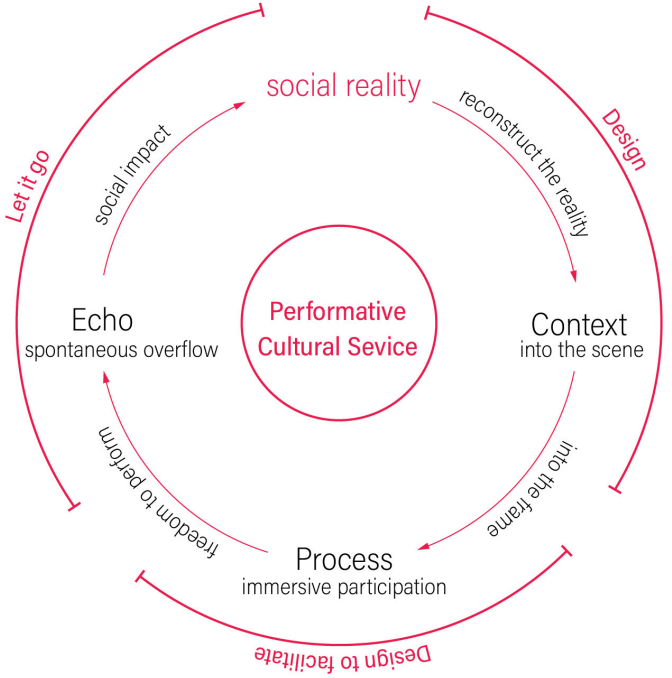

Figure 5. Performative cultural service experience could be divided into three stages: Context, Process and Echo.

According to the case study and literature review, this paper proposed a theoretical framework for enhancing the performativity of cultural service (Figure 6). After analysis relevant cases with these three stages, more detailed factors and potential strategies for

design intervention are identified in each stage. After that, the framework and strategies have been reframed into a set of toolkit for relevant design practices, which has been tested in a two-day design workshop for the Wuxi Museum in 2020 at Jiangnan University, China.

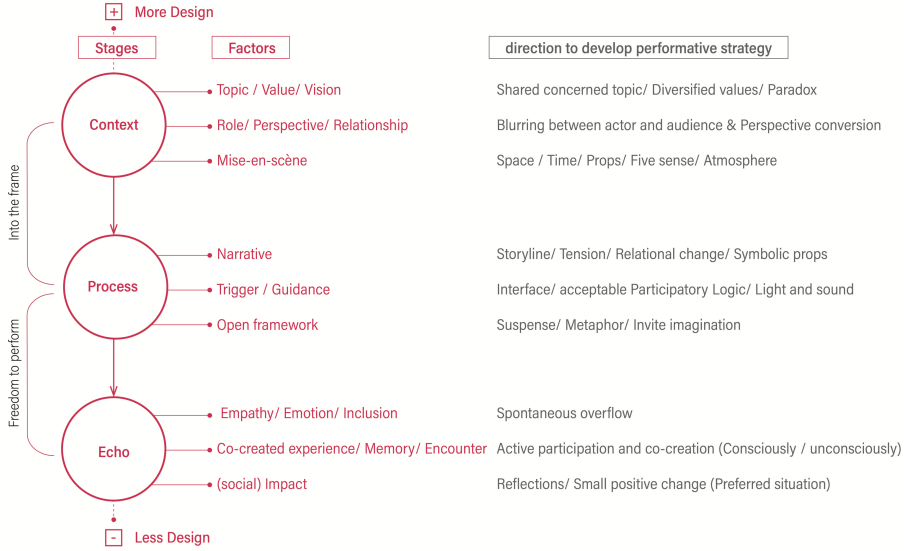

Figure 6. An initial meta-design framework indicating different stages and factors of performative cultural service experience.

- Context: Context serves as the base of the performative interpretation, including topic, role and perspective presetting, and Mise-en-scène. Local museums could select shared concerned issues as the topic and reconstruct them into situated context. In the stage Context, visitors' role and perspective will also be preset, which could be the basis of narratives. With the same scene but with different roles or perspectives highlighted, a drama would achieve different effects, focuses, and interpretations. For example, visitors consciously take the role of the blind before the experience of Dialogue in the Dark to obtain others' perspectives. That is a perspective conversion technique "from the third to the first perspective." Meanwhile, Mise-en-scène like settings, time and space, and atmosphere could lead users into the scene and prepare for an immersive experience. In this stage, the designer is a context-provider who creates a context that supports story-making. A situated context is essential for leaving a memorable experience in the minds of those who visit it.
- Process: The storyline slowly unfolds in the second stage, leading visitors to reveal the immersive narrative with guidance and triggers gradually. Technology could empower the visitors in narrative, activate the visitors as one part of the

history or a witness of a process, lead or provoke visitor's exploratory behavior in revealing the storyline with hints and instructions, as well as personalize the story with user's interaction. In this stage, the design focus is to reconcile "narrative" and "interactive", that is, the contradiction between the linearity of reconciling narrative and the nonlinearity of participants. Narrative is the product of top-down planning by designers, and interactivity requires users' input and contribution from the bottom up. To achieve well-designed interactive narratives, a balance is required between the freedom to interact when we perform and the structure that is imposed on us by our environment to create natural and memorable experiences. Thus, an open framework is indispensable for inviting visitors' own interpretation and imagination. As sense is co-produced by designers and visitors in this stage, designers could never control the whole process, but facilitate visitors' participation and optimize the balance through iteration.

- Echo: Echo refers to visitors' internal participation before fully detached from the experience, as well as their following active behaviors that respond these experience. The first two layers can be designed in advance, while the relation, reflection, emotion or other impact in stage layer is improvise, which cannot be designed but facilitated. As a successful performance is co-created by designer and visitor, the emotion and the "performance" of audience is spontaneous overflow, that designers cannot design or control , but facilitate the process and let it go.

5. Conclusion

This interdisciplinary research explores the complexity of service design by investigating performativity as a language of service encounter and addressing social issues like social cohesion in the context of local museums. Through interpreting cultural service experience as a sense-making activity, this paper is committed to breaking pre-established methods for service design like user journey and touchpoints and proposing a theoretical framework for designing performative cultural service and the directions to develop relevant design strategies. All these results have been tested during a design workshop in Jiangnan University, Wuxi, China. This paper presents a reflection of the role and the future of local museums in the digital age.

Solid perspectives and optical corrections of spaces in graphic & architectural design

Tommaso Empler, Adriana Caldarone, Alexandra Fusinetti
Sapienza University of Rome, Italy
tommaso.empler@uniroma1.it, adriana.caldarone@uniromna1.it,
alexandra.fusinetti@uniroma1.it

Abstract | Since the coding of perspective, there are many design solutions where "solid perspectives" and "optical corrections" are used to correct visual perception of spaces. Some applications are in urban areas, such as Piazza del Campidoglio by Michelangelo (1538) or Piazza San Pietro by Bernini (1629-57), others are in courtyards or small outdoor spaces, such as the Perspective Gallery of Palazzo Spada by Borromini (1652-53), and in theatrical scenic spaces, like the Olimpic Theatre in Vicenza by Palladio (1580-85). Today "solid perspectives" and "optical corrections" of spaces are used in "graphic & architectural design", where "Projection Design", "Exhibit Design" and "Graphic Design" also converge. This paper makes us reflect on the possible future developments of "solidperspectives" and "optical corrections" of spaces, and it assesses whether they will be limited to the field of ephemeral design or will also be part of more lasting solutions over time.

KEYWORDS | GRAPHIC DESIGN, ARCHITECTURAL DESIGN, ANAMORPHOSIS, PERSPECTIVE

1. Introduction

“Solid perspectives" and "optical corrections" of spaces are applied to architecture (Clemente, de Rubertis, 2001), sculpture and painting, and can be distinguished in two different groups: "solid perspectives" are obtained using the principle of vanishing line to correct urban spaces or architectural façade profiles, and they "speed up" or "slow down" effects of natural perspective; "optical corrections" refer to compensation of visual errors, through use of corrective methods closely connected with geometric optics and with physiology of human ocular system, including among these "anamorphosis".

"Accelerated perspective" is used to configure a space where, with respect to the observer's position, sides of the elements that make up the space are convergent with respect to the center of perspective framework. The space appears less deep than it is in reality. Anamorphosis is a distorted projection or perspective, requiring the viewer to occupy a specific vantage point: the space or the image are not recognizable if the observer is not standing in the right vantage point.

These methods, especially in urban field, have been used, since ancient times, to modify perception of spatial extensions in urban spaces. Purpose was, materialized in baroque urban concepts, to exploit the artifice to emphasize some scenic and expressive effects.

In fact, were studied spaces composition and their representation in function of the observer, especially in cases where figurative spatial needs were considered of greater importance than functional ones.

Ways and methods with which illusory perspective and optical corrections can transform spaces, flanked by new technological solutions, are nowadays often adopted for temporary interventions or installations. They have the same purpose as in the past: not rational, but perceptive recomposition of the urban space induces, in the observer's mood, a feeling of astonishment.
There are many design variations, and fields of application start from advertising, to get to media one, to public events field or they have purely expressive purposes.

2. Use of optical illusions in the past

Use of "solid perspectives" and "optical corrections" has already been expertly used by the Greeks.

Restricting historical field of investigation starting from the 15th century, it is interesting to observe how they are used at different scales: in squares and urban developments, in architectural elements, in decorations and in facade buildings feature.

Among urban developments, some interventions are relevant such as Piazza Pio II in Pienza, Piazza del Campidoglio and Piazza San Pietro in Rome.

Piazza Pio II is part of an urban project planned in 1459 and entrusted to Bernardo Rossellino, Leon Battista Alberti's disciple at the behest of Pope Pius II.

The small square, seen from city hall portico, is in "anti-perspective". Square's shape is trapezoidal, whose sides diverge towards the facade of the Duomo. In this way it is perceptually regularized square's shape, which is perceived as a wide and short rectangle and not as a trapeze. On the other hand, when the observer leaves the Duomo, it appears deeper with an "accelerated perspective".

Michelangelo Buonarroti used the same trick for Piazza del Campidoglio in Rome in 1538. The square is trapezoidal with larger base located on Palazzo Senatorio. This generates a "slowed perspective", compared to the point of view from the staircase that leads to the square, and Palazzo Senatorio appears closer. Such geometry transforms into a regular space the 80° angle existing between Palazzo Senatorio and Palazzo dei Conservatori, whose position is required by existing hill's shape.

In San Pietro's square Bernini (1629-1657) had to solve a visual problem: the Basilica was disproportionate, and the dome had lost its ancient central position. The construction of the new colonnade and the square had to necessarily move away the point of view, to allow a perception of the dome in its entirety (which is no longer visible today due to the construction of the Maderno's facade). Bernini uses a "slowed perspective", through the creation of a trapezoidal space perceived as rectangular.

Solutions adopted by Michelangelo for Piazza del Campidoglio and by Bernini for Piazza San Pietro were effective: this is demonstrated by printed lithographic images and by landscape painters, who represent "trapezoidal" spaces of the two squares as "rectangular", and they do not represent deformations that are present in reality.

Although it is not a real urban space, it must be mentioned the Perspective Gallery of Palazzo Spada by Borromini, who in 1635 created an "accelerated perspective". Thanks to converging sides of space and converging floors and vault's plan, he is able to compress an illusory space of about 35 m in a space of 8.82 m long. Arches and columns that surround the Gallery, at the entrance are 4.10 meters high and the vaults are 2.95 meters wide. At the end of the tunnel they reach a height of 2.45 meters high and a width of 1 meter. Illusion is possible because the plans converge in a single vanishing point; thus, while the ceiling descends from top to bottom, mosaic floor rises.

Among buildings decorations there are both "accelerated perspective" in architectural elements or parts realization (such as portals, windows or fake windows), and "anamorphosis", which often replaces elements that are not made due to lack of space or due to financial shortcomings. Some examples are Santo Spirito's portal by Bernini in 1664, Palazzo Barberini's windows (1625-1633) and Palazzo Doria Pamphili's windows (1644-1650) in Piazza Navona.

If solid perspective is often used in urban contexts, anamorphosis is an expedient often used indoors (a significant example of "anamorphosis" is visible in the fake dome of Sant'Ignazio of Loyola's church, built by Andrea Pozzo in 1685). In urban spaces, its use is limited to architectural elements on facades of buildings, often in version of "solid anamorphosis" (Figure 1).

Figure 1. Example of solid anamorphosis in a portal located in Pézenas, France. The building placed along a narrow and uphill road; it is perceived in its entirety only from a main observation point. Thanks to anamorphic deformation of edges, the portal can be perceived in the "correct" proportions. Images from web (Pinterest).

3. Solid Perspective and optical corrections in “graphic & architectural design”

Urban scene today is made up of existing buildings, and to improve architectural space’s quality, whether in urban regeneration or in artistic performances, graphic and exhibit design are used to improve and change spaces perception. Built space is transformed into a

set-up space and "illusory" effect of exhibits, based on same principles theorized in Renaissance and Baroque period, is also evolving thanks to new possibilities offered by technological evolution. In this way are configured so-called “Augmeted Space” or “Spatial Augmented Reality” (Maniello, 2018), which define a new type of public space: it arises from overlap between computer data and real space, visible in overlapping layers (Manovich, 2006). One of preconditions for the configuration of these new spaces is the continuous dialogue between real and virtual space through the development of contents.

The research investigates how it is possible to use "solid perspectives" and "optical corrections" and in which fields of application, regard from those of the past, and investigates what possible future developments will be.

In "projection design" field, "video mapping" applications, integrated with lighting systems, give rise to visual communication actions. Content information can relate to objects where video projections are made (Cultural Heritage). These forms of communication are also called "interactive light".

Main feature of "video mapping" is the close relationship between the support on which to perform the projection and information content: we often operate on buildings facades helping to define scenographic and optical distortion effects of the facade itself, thus engaging a mutual relationship between observer, space and artistic creation. As it was in the past, this solution allows to concentrate the attention of the observer on the global effect of perception.

Interesting examples are present in Rome. In via dei Fori Imperiali there are seasonal projection mapping installations which tell the story of the August’s and Caesar’s Forum with different ways of involvement.

In video projection of August’s Forum, the viewer, while he is sitting on a tribune located on the edge of the archaeological excavation, attend the story of Forum evolution and the history of Roman Empire. In the Forum of Caesar, on the other hand, the viewer moves among archaeological finds and, as he passes, video projectors, that reconstruct the history of the place, are activated. Tour ends in front of the Curia, where political decisions of the

Roman Empire were made, and "projection mapping" virtually breaks through the wall placed in front of the visitor, telling the transformations of the building over time.
Video projections overlap archaeological finds and reconstruct place's history making space's articulation and space's glory understandable to the visitor, as they were 2000 years ago.

"Projection mapping" is also used in limited periods on some facades of historic center of Rome, through artistic installations active at night, such as RoMap in September 2015 and 2016, or "Videocittà" in October 2018 and 2019. Facades are considered palettes, even if correctly mapped, where video artists release their inspiration. It is possible to add three-dimensional effect to video mapping, through stereoscopic images in the colors dominating the vision with anaglyph glasses (Figure 2).

Figure 2. Nerdworking, Solid light Festival, 2018, Basilica of Sant'Agostino in Campo Marzio, Piazza di S. Agostino, Rome. Video mapping with stereoscopic images viewable through the use of anaglyph glasses. Image by Adriana Caldarone.

Space becomes scene of a multimedia "dramaturgy" where projections are main element.

In addition to expressive content, informations content of videos are often also linked to the support: both visual and sound storytelling turns to the history and function of the building, in a unitary project of lights, audio, and architecture.

"Projection design" linked to the "projection mapping" therefore presents some

fundamental, conceptual and technical elements: conceptual aspects are linked to "storytelling" and "storyboard"; technical aspects are related to survey and 3D rendering restitution in order to know the object to be "mapped", type of video projector and its position used to "map" the object. Storytelling is a communication technique that consists of telling a story to attract the attention of a specific audience. A message is conveyed to that audience, to stimulate a certain desire in the spectators and to persuade them to perform a specific action. In few words: it's about persuading by telling a story (Scuratti, n.d.). Storytelling elements are (Nordio, n.d.):

- restrain emotions related to the story you want to tell;
- stimulate the senses to tell the story;
- put "why" at the center of history;
- create in the visitor's mind a new world or a new conception of the object being told;
- tie history to identity values;
- does not aim to convince but to involve;
- activate lateral thinking.

Storyboard provides the structure of projection mapping. It is a timeline, where individual scenes are sequenced, while providing their duration. Elements to be defined are:

- subjects in the frame, and their sequence;
- information to be transmitted (linked with storytelling);
- time between one storyboard scene and the next;
- position of the frame and if it is static or dynamic.

From a technical point of view, geometrical study and architectural survey are two essential issues in "projection mapping" design on an architectural structure. Design consists of several stages of construction and includes (Empler, 2018):

- survey of the support with direct or indirect method, where to carry out video projection. Choice of survey methodology depends on a number of factors (complexity of object to be "mapped", in terms of dimensions and details on facade). For simple objects can be used a direct method survey (it is carried out with use of traditional tools) and a photographic survey of the surface on which to project. More complex objects, such as church facade or archaeological objects, need an instrumental survey method through a 3D laser scan or a photo-modeling process. Aim of survey is to generate and control a virtual 3D model;
- generation of a measurable 3D mesh model, virtual replica that is overlap (even if scaled) to real object at the base of survey. On this 3D model it is necessary to carry out subsequent processing and transformation operations to create the performance;

- study and realization of geometric transformations, whose purpose is to make virtual 3D architectural model coincide with the real one. In this case, some principles of descriptive geometry are applied such as homotety, homography and anamorphism.

Homotety is a geometric transformation that allows a space expansion or contraction, while maintaining shape, angles and does not change relationship between them.
Having as a point of reference homotety, we continue with a homographic transformation of the object of interest, generating a second space whose points exactly correspond to those belonging to the architecture taken as a reference point. Once the animation is designed on the detected space, an adaptation of the image projected on the architectural surface takes place to correct any aberrations, the so-called "wrapping". Generated illusion consists of an image reproduced in a distorted way on the surface so that it can be perceived correctly by the observer from a main point, through the rules of anamorphism. Thanks to this methodology, architecture becomes “liquid”, mobile, it adheres as if it were a film, it deforms and detaches itself from real surface.
"Projection mapping" is a new frontier of art, technology and visual design applied to cultural heritage. It is an advanced projection technique, which transforms any type of surface into a dynamic display, transforming architecture into a new communication media. Animations, videos and light effects can communicate an advertising message, information or history of an object or environment. What you can achieve is an explosion of images, capable of totally involving the viewer. Each event is able to turn into a real mass illusion.

"Exhibit design" is another fields where we create three-dimensional installations, and where two types of solutions prevail: optical illusion through anamorphism, in a sort of "solid anamorphosis"; installations where we use "accelerated" or "slowed" perspectives, as in theatrical scenes ("solid perspective").

In the past, anamorphosis was often used in a symbolic key to spread a subliminal or hidden message (i.e., painting "The ambassadors" by Hans Holbein, where a skull in anamorphosis is visible, and communicates the inevitability of death); in the same way nowadays it is used for diffusion of a message, especially in advertising or for promotion of events.

In fact, emotion of optical illusions generates sharing and virality among users (especially on social networks), who, unknowingly, become a means and instrument of promotion and marketing of the event, an object or the artist. Examples are two exhibitions held in Paris, such as "Qui Croire?" by François Abelanet in 2011, installation of a green area in front of

Hotel de Ville in Paris (figures 3), or a 2014 installation at the City of Science and Industry of la Villette.

Figure 3. "Ephemeral garden", July 2011, Hotel de ville de Paris square. apparently it is a garden whose shape you cannot recognize. If you look at it from the main point, the garden is a globe with meridians and parallels. Images from web (artistasaturnino).

In Paris also, the Louvre Pyramid was used for two different artistic installations, one in 2016, the other in March 2019, on the occasion of the 30th anniversary celebration of the Pyramid of Pei. In the first case, a street artist has glued on one of the pyramid's facade, strips of paper with the pattern of the museum behind it. The overlap of the real and anamorphic picture, from a main point, cause, in an optical illusion, the disappearance of the pyramid (figure 4).

In the second installation, the street artist used strips of paper around the pyramid with a group of volunteers. The effect is an anamorphosis, visible from the top, that (in an illusionistic way) sinks the pyramid below the walking level (figure 5).

Figures 4. JR, Louvre Pyramid, 2016, Paris. On the left, construction's picture of the installation's construction site on pyramide facade; on the right, the overlap effect of the anamorphosis. Images from web (artribune).

Figure 5. JR, Louvre Pyramid, 2019, Paris. On the left the installation seen from a zenithal photo. On the right Anamorphosis seen from the correct visual point. (The hexagonal shape perceived from main point, is actually a polygon composed of a rectangle and a trapezoid). Images from web (artbooms).

In "Graphic Design" field, creations are mainly two-dimensional, with realizations of solid perspectives and/or anamorphosis and/or use of ambiguous figures, as in the realization of Marseille in 2013, on the Stock Exchange and Chamber of Commerce by Pierre Delavie , or anamorphoses in urban landscape created by Felice Varini or by the Madrid-based collective BoaMistura (in Saint Paul's favelas in Brazil). In Saint Paul favelas it is a real urban redevelopment thanks to the use of graphics and anamorphosis: walls were painted, with collaboration of inhabitants of neighborhoods, with brightly color tones and large letters compose words that recall positive sensations (figure. 6). The aim is to reinvigorate the

consciences of the most disadvantaged neighborhoods in São Paulo. Anamorphosis becomes both the means of transmission and the container of the message.

Figure 6. Favelas, São Paulo, *Brasil. Letters are painted through anamorphosis by the artists and locals. Images from web (disup).*

4. Conclusion

Solid perspective and optical illusions are still alive instruments thanks to modern interpretations and application fields. They are not abstract conceptions of descriptive geometry, but have a large application fields in planning and design of collective spaces. If in the past architects, artists and writers collaborated each other to study and create illusory spaces, today many more skills are integrated: designers, architects, sound designers, collectives of artists, video makers, computer scientists, street artists, performers and so on. People is often involved through active performances. Design of public spaces develop into collective moments of construction, fruition, and sharing of space. An experiment of global connection which, through perspective tools, comes to transformation, though ephemeral, of built heritage.

Spatial construction for ideational meaning: An analysis of interior design students' multimodal projects

Andrew Gill[a], Giovanna Di Monte-Milner*[b]

[a]University of Johannesburg
[b]University of Derby
*g.dimonte@derby.ac.uk

Abstract | Multimodality is an inter-disciplinary approach that considers communication to be more than just language. Multimodal studies focus mostly on the analysis of two-dimensional printed, digital, and screen production. This paper explores a multimodal pedagogic approach used to teach students to create interior design projects as three-dimensional ensembles, which we reflect upon to contribute to the framework of multimodality. This qualitative research begins with a review of multimodal discourse establishing language as a system of choice, and a relationship between spatial design and language. A case-study of students' multimodal ensembles reveals how the design choices of mode, semiotic resource, modal affordance and inter-semiosis led to students producing rich and inclusive meaning, supporting a reproductive health mandate. An interpretive semiotic framework based on Hallidayan principles of Systemic-functional linguistics is developed for spatial meaning-making analysis for future projects. The findings offer a narrative metalanguage for spatial meaning-making, contributing to broader interior design discourse.

KEYWORDS | MULTIMODALITY, INTERIOR DESIGN, SYSTEMIC-FUNCTIONAL LINGUISTICS, HIV/AIDS AWARENESS, GUERRILLA MARKETING

1. Introduction

Multimodality infers that communication and representation is greater than just language, and relies on a multiplicity of modes (visual, spoken, gestural, written, three-dimensional, etc.) that people use to make meaning and to communicate with each other. Multimodal Discourse Analysis (MDA) considers how multimodal 'texts' make use of a variety of modes of communication to make meaning within the sociocultural context in which they occur. The aim of MDA is therefore to describe the socially situated semiotic resources that people draw upon for communication (Paltridge, 2012). The four key concepts that provide the basis for all MDA are: Mode, a medium of communication that is culturally shaped over time through its regular use in society; Semiotic resource, a means of meaning-making that display regularity in the way it is used; Modal affordance, what it is possible to express and represent easily with a mode, and Inter-semiosis, how modes are arranged (or designed) in a particular context (Bezemer, 2012). Understanding these concepts and their interrelationship is critical in determining how communication functions in any particular time and place, how it is produced and by whom it is produced.

The rapidly developing interest in multimodality studies reflects a shift from discipline specific to thematic structures with inter-disciplinary collaboration becoming increasingly important to address current social challenges, the democratization of knowledge, and to accommodate for emerging new forms of digital communication. Within Multimodality studies there is a stronger correlation between theory and practice with an increased focus on developing solutions to real-world problems across a range of domains, revealing a change of relationship between academia and the wider society (O'Halloran & Smith, 2011).

Currently, the majority of literature focuses on two dimensional forms of multimodal discourse with far less relating to the analysis of three-dimensional and spatial modes of communication (Forceville, 2010; O'Halloran, 2008; Stenglin, 2004), to which this study wishes to contribute. The aim of the paper is to present students' spatial design proposals that can be seen as rich meaning-making ensembles or 'texts', reflecting a set of choices made by the designers through the selection and arrangement of multiple two and three-dimensional semiotic modes, (e.g. text, sounds, colours, images, forms and texture, etc.), within a specific social context. This is done to demonstrate that three-dimensional spatial design (as an interior design practise) can contribute towards multimodality theory. We developed a 'matrix of choice' analytical framework based on the Hallidayan principles of functional linguistics. This framework is used to analyse how meaning is made in these spatial modes of communication, designed to raise awareness about HIV, and related social problems.

In this paper, we firstly present an overview of multimodal literature to theoretically position the study. We then present a background to a multimodal pedagogical approach used for the student project, purpose and objectives. Thereafter, we describe the research design and methods developed for analysing the described data, followed by an analysis of selected student's proposals using an interpretive Systemic-functional linguistic (SFL) framework to

describe how the meaning is made in the student's multimodal ensembles. We conclude with a discussion on the implication for multimodality discourse and its impact on Interior Design studies.

2. Multimodality as the theoretical positioning of the study

Multimodality, Multimodal Semiotics and Multimodal Discourse Analysis (MDA) are terms used to describe the interdisciplinary approach to the study of language that extends the concept of language beyond the written and spoken word, to include images, symbols, gesture, action, music and sound (Cope & Kalantzis, 2009; Jacobs, 2007; New London Group, 1996; O'Halloran, 2008). These terms are used to describe the study of any form of communication (media, mode, semiotic resources) other than the perceived dominant forms of written and spoken language (Bezemer, 2012). Multimodality theory draws on a social semiotic approach to language, to deliberate how multiple modes of communication in the form of 'texts' are used to make meaning (Bazalgette & Buckingham, 2013; Jewitt, et al., 2016; Kress, 2011). Kress (2011, p.36) explains

> "…texts, of whatever kind, are the result of the semiotic work of design, and of processes of composition and production. They result in ensembles composed of different modes, resting on the agentive semiotic work of the maker of such texts"

Whom the author is and how the author uses multimodal forms of communication is a key concern of MDA. It is stated that:

> "…people use semiotic resources both to produce communicative artefacts and events and to interpret them ... in the context of specific social situations and practices" (Van Leeuween in O'Halloran, n.d., p.2).

According to Jewitt (2009) multimodality theory is formulated upon the following four assumptions:

- Representation and communication always draws on a variety of modes, all of which equally contribute towards meaning-making;
- Each mode of communication realizes different meanings;
- People orchestrate meaning through their selection and configuration of modes;
- Semiotic resources are shaped and refined over time by the social conventions specific to the genre, context and time.

Michael O'Toole, who pioneered the development of analytical semiotic models for application in MDA, based his analytical framework on Halliday's theory of SFL, notably *paradigmatic dimension* and *metafunctional dimension*. The principle of *paradigmatic dimension* implies that the user has choice for meaning-making and selects from available options within the environment (Halliday, 2003). Halliday's three metafunctions of language are described as:

- *Ideational* or *experiential* function, relating to the need for people to make sense about the world around them and within;
- *Interpersonal* function for creating and maintaining relationships;
- *Textual or compositional function*, which acts on how the other two modes are arranged to create a coherent flow of discourse.

3. Background to the student project, the brief objectives and modal influences

This annual student project forms part of a larger Curriculum-integration strategy developed by the Higher Education HIV/AIDS Programme (HEAIDS) in South Africa. The HEAIDS was established as a

> "…dedicated national facility to develop and support the HIV mitigation programmes at South Africa's public Higher Educational Institutions" (HEAIDS, 2012, p.2).

This sexual reproductive health initiative is driven by government policy in response to the alarmingly high rate of HIV/AIDS infections in the region (UNAIDS 2019) and was implemented because "the age group most affected by the pandemic regrettably feed into the workplace and institutions of higher education" (Gobind & Ukpere, 2014, p.355; Shefer, et al., 2012). The University's Interior Design department's students regularly participate in this programme, in collaboration with the Institutional Office for HIV & AIDS (IOHA) whose officers are responsible for conducting workshops and educating students about reproductive health and wellness.

The brief outlined the project's objectives of designing a multimodal spatial intervention that could promote HIV/AIDS awareness, lead the viewer to the various IOHA offices and services, and disseminate information. The specific design requirements required the students to: identify and analyse a suitable location on campus, create an original slogan/message for the appropriate target market (staff and students) using their own popular voices.

The students were encouraged to incorporate into their projects[1] visual and spatial modes of communication used in related, art, design and marketing disciplines namely: exhibition-stand design, installation art, and guerrilla marketing (GM). Some of the similarities between these modes of meaning-making is that they use multi-modalities to stun, attract and engage the viewer, make use of popular and positive catchy message and encourage consumers to disperse the message. They require high levels of creativity (Hutter &

[1] All work produced by students as part of normal coursework remains the property of the university and therefore permission to use it for academic or marketing purposes is not required.

Hoffman, 2014), imagination and innovation in order to effectively engage consumers (Nufer, 2013) or viewers at a personal and memorable level; make use of the environment and its physical surfaces to convey messages (Gambetti, 2010); are usually temporary installations, and are defined by their ambient conditions.

This strategy adopted for the project brief was intended to produce an outcome that was meant to produce more than just a prototype of a multimodal awareness campaign or to tell a story. The intention here was to get deeper insight into the students' understanding of the pandemic and related social ramifications, allowing them to express themselves, and communicate in ways that might otherwise be inhibited when using more traditional linguistic methods.

The project was conducted in collaboration with IOHA who first workshopped HIV/AIDS-related themes with students and consulted with students during the development of their proposals. For final submission students submitted both two-dimensional documentation, and a three-dimensional scale model of the proposed intervention shown in relation to the existing building structure.

4. The research design and methods

This qualitative research design is ontologically interpretive and epistemologically subjective, falling within the constructivist paradigm. The authors present their research bias being facilitators of the student project over several years.

Firstly an initial review of literature is conducted to situate the study within the field of multimodality, and to establish the relationship between spatial design and language. We explore the Hallidayan principles of SFL. These include a) *paradigmatic dimension*, (meaning is choice), elaborated upon in the literature review, and b) *metafunctional dimension*, (ideational, interpersonal and textual/compositional). Halliday's SFL, is an approach to linguistics that considers language as a social semiotic system (Paltridge, 2012). A case study approach is taken to analyse a selection of student's proposals according to an analytical framework developed on Halliday's metafunctions of language.

4.1 Data and delimitations

The data analysed includes the scale models, plans and sections of two selected design proposals resulting from the student project (explained to be based on the reproductive health programme). These samples were selected as they successfully illustrated the learning outcomes of the project, and used multiple visual modes of communication. The primary data comprises of photographs of students' three-dimensional scale models (taken by the authors) that represent the existing location and its structural constraints, as well as their proposed installation.

The data included an architectural type floor plan and cross-section, indicating circulation, dimensions and structural components. The data is referred to as proposal 1 and proposal 2. We acknowledge that two-dimensional photos of three-dimensional models are only representations of a proposed spatial intervention. The photographs are taken from a fixed view point, in some cases students digitally superimposed an image of the model into an image of the existing building to create the illusion of a full-size installation.

5. Analysis of student projects

On completion of numerous iterations of this project over several years it became apparent that there was a need to develop a more substantial analytical framework, and language that could be used to analyse and describe how the design choices made by the students regarding the selection and arrangement of visual and spatial modes was used to make meaning. The development of a SFL framework could provide a useful aid for future teaching and learning, development of briefs and associated learning outcomes, and evaluation of projects in the interior design studio.

For this we borrowed heavily from O'Toole's analytical semiotic models for application in MDA. O'Toole used the principles of SFL to develop an empirical method for the analysis of various modes of visual meaning-making bringing a "fresh and theoretically powerful social semiotic perspective of systemic functional theory" (O'Halloran & Smith, 2011, p. 5) that could be applied across a wide range of disciplines. Acknowledging that each "domain has its own expertise, and registerial conventions of theory and practice for research and discoursing" (O'Halloran & Smith, 2011, p.5), this approach may be more accessible, and has universal application. O'Toole initially applied this analytical tool to painting and later adapted it for analysing other art forms such as, architecture and sculpture (2011). A further example of its application and development can be seen in O'Halloran (2008) for digitally produced graphics and video screen productions, and Riley (2012) for Fine Art drawings. Formulated on these principles we attempt to develop an analytical framework that can be used to analyse how meaning is made in the students' multimodal proposals. This analytical tool allows one to itemize a multimodal ensemble into smaller components and then describe each according to Haliday's three metafunctions of language, *ideational, interpersonal* and *compositional*.

Our developmental framework and two examples of its application are presented below.

Table 1. This table presents a matrix of choice analytical framework where the Ideational function relates to the designer's understanding of what HIV prevention is in this social context. The Interpersonal function is indicative of the designer's stance and attitude towards HIV prevention and the mood with which it is conveyed to the viewer. The Compositional (or textual) function deals with the arrangement of available visual and spatial devises, or inter-semiosis, by which means the other two functions are realised.

Design Component	Function		
	Ideational	**Interpersonal**	**Compositional**
Textual message	Statistical Factual Thematic General / Targeted Sexual Medical Social Cultural	Intriguing Intimidating Imaginative Speculative Reflective Commanding Questioning Warning Provoking Playful	Size Colour Placement Position Repetition Typography Emphasis Word composition Rhyming Tone
Spatial structure	Location Contextual integration Placement Access Formal - ordered Casual - creative	Visual metaphor Thematic Narrative Scenographic Didactic Degree of transformation Surprising	Materiality Colours + textures Dimensionality Organic / Geometric Layout Circulation Containment Shapes + forms
Additional media	Realistic / Abstract Figurative Metaphoric Numeric Illustrative	Symbolic Conceptual Suggestive Descriptive Narrative Hyperbolic	Emphasis Multi-modal mix - 2D or 3D media Repetition Directionality Placement + size Colour
Intended user engagement	Participation or observation Imposed / Voluntary General / Targeted	Level of complexity Cooperative Competitive Physical/Emotional/Cognitive Supplementary / Essential	Diffusion Physical / Virtual Analogue / Digital Degree of interaction Privacy Proximity

To create a sequential approach for the analysis of the multimodal design proposals it became necessary to sub-divide the ensembles into smaller design components as listed in the first column in Table 1. It is important to understand that the matrix of choice analytical framework is systemic in nature. This means that the ranges of available choices do not only allow meanings to be negotiated within a single function or restricted to only one component of the multimodal ensemble, but "…allow for the negotiation of meanings

through all functions at all levels", (Riley, 2012, p.5) . As in any form of multimodal 'text', all these functions operate simultaneously.

Figure 1. Proposal 1 - "Stomp out HIV" courtesy Rosetta Mpufo, 2018, © University of Johannesburg. Photograph (by author) of a scale model of a multimodal spatial intervention (colour), placed in relation to an existing building structure (white).

Many student's conceptual starting point is a slogan, as appears in this case. The target is *general* and the message is *commanding* in its appeal to eliminate HIV. The text is integrated into the structure in two components. 'Stomp out' appears as flat cut-out letters attached to the underside of the sole accentuating the action it describes. All the text is emphasised through *colour*, and *placement*, the additional enlarged *size* and three-dimensionality of the letters HIV, make it the focal point, and the topic obvious. The use of irregular and distorted fonts is intended to be reminiscent of a horror movie poster. The implied meaning is that HIV is something evil and needs to be eliminated or 'squashed like a bug' under the sole of one's shoe. The informal *typographical* solution of the text makes it appear less authoritarian to resonate with the target. The IOHA and university logos (as required) are integrated through *size and placement* with reduced significance, giving it institutional endorsement.

This spatial structure's *location* is an empty entrance foyer space through which most users of the building will have to *circulate.* The central prominent placement will require

pedestrians to walk around the structure, creating forced engagement. The scale is intimidating and indicative of the extent of the problem. The blackness of the sole and exaggerated tread, as on an industrial boot, is both serious and heavy, as is the topic, and articulates the gravity with which it needs to be dealt. The vertical dimension (approx. 3 meters) restricted by the ceiling height creates visibility from a distance, and adds *hyperbolic* meaning to the magnitude of the effort that is required to eliminate HIV. However the 'message' may not be so clearly read from all approaches. The organic black shape of the structure contrasts the monochromatic geometric interior in which it is *contextually integrated*, adding emphasis through its contrasting form. The black glossy reflective surface of the *material* creates a sense of hard, unforgiving edginess. The reflected shape on the floor helps contain the elements and is reminiscent of a shadow of gloom, a big black cloud hanging overhead to be avoided.

There is no additional media used in this ensemble.

The inter-semiosis or composition of modes results in a *visual metaphor* in which the visual and literal meaning correspond seamlessly, creating a clear and coherent multimodal message. The user engagement is both *imposed* and *physical* due to proximity, is intentionally *intimidating* due to scale and colour and strives to create an *emotional* shared spatial experience. The overall message is meant to be uncompromising and *didactic,* demanding that the viewer participates in eliminating HIV.

Figure 2. Proposal 2 – "Don't hip hop without a drip drop" courtesy S. Jacobs, 2016, © University of Johannesburg. Photograph (by author) of a scale model of a multimodal spatial intervention, superimposed onto a visual of the existing space.

The second proposal's message uses wording that has *medical* and *cultural* references. It aims to encourage the viewer to continually do medical HIV/AIDS tests, especially if they regularly change their *sexual* partners. The message seems *playful* and resonates with a particular *culture*, evoking a sense of playfulness, made possible by the *imaginative composition of words*, which rhyme, in a popular *tone*. The *typography* used helps to reinforce the message as a *warning.*

This particular interior ramp is utilitarian, and seldom showcases any design or information, and is *located* next to busy studio environments. It is fully *integrated* into its existing surrounding *context*. This is done with the use of cuboid forms which make up the signage overhead, and 2D symbols, inserted on the wall and floor. The *access* is from two sides, and the repeated message is thus multi - *directional*. The viewer is forced to *circulate* through the space until exiting at the other side, reinforcing the message over time.

The additional media used, includes *two-dimensional* symbols used on the floor (dance routine steps) and wall planes. The first symbols (arrows and footprints) are arranged in a *directional* sequence on the floor, suggesting an experience of entertainment, and instigating feelings of playfulness for the viewer. A set of life-size *figurative* dancing shapes are placed on the wall in *repetition*. They are *suggestive* and *metaphoric* for swapping partners. The repeated female figure in red, is *symbolic* of an infected person spreading the HIV/AIDS to multiple partners. The *repeated* use of the IOHA logo imagery is intended as an official branded reference to a service, thereby *diffusing* the message.

The level of engagement in this proposed intervention is intended to be *observational* (one does not need to participate in any other way). Engagement is *imposed*, as the viewer navigates down the ramp. Engagement is *general* (not targeted to a specific group), and is meant for anyone using the ramp. The experience is *cognitive* and *physical* for the viewer who is engulfed in, and navigates a *complex* set of media.

To conclude, this section presents examples of two narrative analytical descriptions of multimodal spatial texts according to the matrix of choice framework as interpreted individually by each author to demonstrate how it might be used.

6. Results and discussion

The research findings are presented as qualitative content analysis in the form of narrative descriptions of the meanings made through the use and arrangement of multiple visual and spatial modes using the matrix of choice analytical framework presented in Table 1. The use of this table (developed from SFL principles) proved a useful tool for describing how the meaning was made in the spatial-interventions analysed above when read as multimodal 'texts'. It provides an alternative method of describing how the design of these ensembles relied on the agentive semiotic work of the student, and encouraged the use of the students' own voice in a creative and expressive manner. Based on our test case we are of the opinion

that this SFL approach can contribute significantly to how we articulate the ways in which meaning is produced. It contributes to the development of a metalanguage used for discoursing the relationship between "material codes of production" and the "production of meaning in a social system" (Drucker, 1998, p.139).

6.1 Benefit in contributing to aids awareness and IOHA's mandate

The multimodal HIV/AIDS awareness proposals produced by the students have been well received by other role players within the university who are mandated to implement the institutional policies on sexual reproductive health education and awareness. These projects are executed in close collaboration with IOHA who drive the process. IOHA often showcase these students' proposal at workshops, seminars and conferences as tangible outcomes of the curriculum integration process. They are used as effective multimodal forms of communication that: provoke dialogue, and visually convey rich original messages generated by the students themselves. They are made available to other disciplines to illustrate different perspectives, possibilities and opinions for adopting alternative strategies to addressing the same problem. They also give valuable insight into the students' response to, and understanding of the HIV awareness programme. Unfortunately very few have actually been translated in to full-size installations mostly due to financial constraints and therefore remain principally academic exercises, as the potential impact of the installations cannot be tested.

6.2 Benefit to teaching and learning in interior design

This multimodal approach can be valuable in the classroom for the development and analysis of future interior projects. It presents a new method of evaluating and discussing outcomes and contributes to developing the discourse related to spatial design. It also teaches students to design spatial interventions that are more experiential and more inclusive of diverse communities, cultures and values, as they enforce their designs with universal images, symbols and text, other than just using typical interior design elements. The success of the multimodal projects in creating meaning is highly dependent on the students' spatial cognition and technical skills in executing the project. Development of these skills is embedded in most interior programmes, however it needs to be noted that some very good initial concepts never manifest as workable spatial solutions or in acceptable presentation formats.

6.3 Broader Implications for interior design

Despite this being a first attempt at using a SFL analytical method, both authors are of the opinion that it could have broader implications for the analysis and reading of multimodal spatial design. This research presents a potential alternative method for analysing meaning-making in built interior installations even though, in this case-study it was applied to scaled models. In practise this could prove a useful approach to determine how visual language

could be implemented in interiors to create meaning, how visual language is shaped by context and culture, and furthermore, it's potential for communication.

7. Conclusion

Through the analysis of these three-dimensional and spatial multimodal proposals produced by students as part of a HIV educational programme, it was revealed that interior design has the potential to contribute to the multi-disciplinary nature of multimodality by introducing aspects of spatial design, which is currently not evident in existing literature.

The multimodal approach was of benefit to IOHA allowing students to express their own voices in modes that cut across cultural and language barriers and in turn produce additional insight into IOHA's HIV awareness initiatives.

The further development of multimodal pedagogies is of benefit for interior programmes which rely heavily on visual communication. A deeper understanding of multimodality can benefit students when required to design meaningful multimodal and inclusive spaces to accommodate diverse communities.

This SFL approach and associated tool that the authors created has the potential to be used to also analyse full-scale interior installations with some adaptation to accommodate for the limitations and constraints associated with built installations. It may also support practice-led research and opens up new avenues for research and possible publications in the Interior Design field.

Tales of Surprise: Exploring Sense Making Processes Through User Narratives

Miray Hamarat*[a,b], Ozge Merzali Celikoglu[a],

* mhamarat@dogus.edu.tr

Abstract | An artifact firstly finds a voice in verbal expressions of people based on how they talk about and through them. Accordingly, products become cultural elements even before they are being used or became part of everyday live. As artifacts and their meanings are built up and contextualized in language; the language frames the meaning of artifacts, which are occurred in using. When a product comes into use, its meaning is created according to how the user interprets that product and communicates with it in a particular context. However, in the product design process, some codes and intended meanings are always assigned for presumptive uses by designers. Whether designers' intentions make sense to users or not is always debatable. Relying on the approach of design semantics, this paper aims to investigate how users make sense of the components of a product, the Surprise Egg, when they are asked to interact with this product in pre-structured scenarios.

KEYWORDS | AFFORDANCE, SENSE-MAKING, USER NARRATIVES, SURPRISE

1. Introduction

The generic concept of the Surprise Egg includes a yellow capsule-like shell resembling an egg's yolk, which contains a plastic toy, and this shell is covered with a layer of chocolate. We chose Surprise Egg since it is a multilayered product consisting of edible and inedible components, which again are distinguished as package and product.

The surprise egg concept raised as the idea of Michele Ferrero in 1968, and in 1974, the Italian company Ferrero turned this idea into a product that could be given to children so they could have a little "surprise" every day, based on the tradition of Easter, in this way also address to children and inner child in adults. ("Kinder Surprise", 2020)

Surprise egg is launched as gift for children and promises three experiences in one product with the "delicious milky taste of quality chocolate, a little toy and a BIG moment of surprise!" ("Kinder Surprise", n.d)

Moreover, it is promoted that these three elements create a world of fun and entertainment that helps children to develop their imagination while reassuring parents at the same time.

As the first step of understanding how users make sense of the components of a product, we looked over how the concept was presented throughout the history. Then, we examined advertisements as another important source to explore how the concept developed in different cultures such as Italian, French, German and so on. For instance, in one of the German advertisements, with the "how mom became the focus of the children's party?" question, it emphasizes that "surprise egg can make you [the mother] a star in the eyes of children" (Figure 1; Advertisement 1). In another example (Figure 1; Advertisement 2), children's happiness is associated with surprise egg. Moreover, with surprise egg you can fulfill your children's wishes at once (Figure 1; Advertisement 3).

Advertisement 1

Advertisement 2

Advertisement 3

Figure 1. How mom became the focus of the children's party? (Advertisement 1); Kinder Surprise fulfils three wishes at once. (Advertisement 2); The happiness that starts with good Kinder chocolate and continues with surprise (Advertisement 3).

In 1980's one of the British advertisements (Figure 2) used the Humpty Dumpty character to refer to the Kinder Surprise, as Humpty Dumpty is a character in an English nursery rhyme and known in popular culture. The character is also a common literary allusion, particularly to refer to a person in an insecure position, something that would be difficult to fix up when it is broken, or a kiddie person ("Kinder Surprise", 2020). Humpty Dumpty also appears in Lewis Carroll's Through the Looking-Glass (1872) where Alice remarks that he is "exactly like an egg"; Alice clarifies that she said he looks like an egg, not that he is one. A similar connection is carried to the advertisement: The surprise egg looks like an egg, however it is not an egg.

Figure 2. A sentient egg, styled in the similar vein of Humpty Dumpty, who murmurs about surprise egg and then suddenly fall from the wall.

Accordingly, it can be claimed that with the surprise egg concept, new associations between egg and surprise are developed for the new generation. At (Figure 1; Advertisement 2), it is shown that the child is shaking the surprise egg to guess what that is inside of it. The same gesture can be observed before opening gift packages.

All above mentioned associations and their presentation generate our consumer culture and in time, they can evolve into different forms in our narratives. Nowadays, surprise egg toys have become collectible for adults as well. Collectors often try to acquire all toys within a themed set. Some even share their unboxing experience on social media or create their own toys and re-wrap them in packaging.

Relying on Krippendorff's statement of "design as sense making" and Sarbin's understanding of the narrative as an essential component of human's world, we explored in a small scale how people make sense of the surprise egg. To do this, we organized and facilitated two

workshops with two different participant groups and collected narratives from the participants. Eventually, we interpreted the process and the outcomes in order to get insight on how two different groups, i.e., children and elderly, respond to the promise of the surprise egg.

2. Methods

Our research examines how two particular user groups, the children and the elderly, make sense of different layers of the Surprise Egg within the metaphor of 'surprise' through a series of workshops. The workshops were conducted at different times and places with the children and with the elderly separately. We visited the children (age 8-9) at the elementary school and the elderly (age 60-65) at the nursing home, which is their residence.

During the workshops, both groups were instructed to perform a number of tasks utilizing the Surprise Eggs. Our data relies on interviews with the participants as well as observations throughout these workshops. For the sensitization, interview topics are formulated to conduct casual conversations (Hassen, 2016).

Besides these informal conversations, follow-up semi-structured interviews were conducted to gain a deeper understanding of our participants' narratives and explanations. Also, observations during the workshop supported our exploration on how our participants were experiencing the Surprise Egg. This method had a particular contribution to identify possible dimensions of variations among the individuals and groups (Lapan, Quartaroli, & Riemer, 2011).

All the data was analysed through ethnographic content analysis. Eventually, we identified particular categories of narratives according to both participant groups. These categories were mainly identified based on concepts such as structures of narratives, reinterpretation and affordance (Gibson, 1977; Krippendorff, 2006; Norman, 1999)

3. Workshops

This study is conducted with two different participant groups through a combination of purposive and convenience sampling. Therefore, we deliberately chose our participants as the children and the elderly based on the distinction between their experience and familiarity with the Surprise Egg: While the elderly had no previous experience with Surprise Eggs, the children were quite familiar with the concept. The workshop consisted of two sessions: The first session which is called "unboxing session" was designed to examine the first interaction of the participants with the Surprise Egg. The outcomes of this session provided us with insight on the following issues: How do the participants read the Surprise Egg and make sense of the package and the product within the context of surprise?, and do

the intended meanings within the product make sense to the participants who had no previous experience with the Surprise Egg? Following, in the second session the participants were required to build new artifacts by up-cycling the egg-like shells of the Surprise Eggs. The second session is called as “up-cycling session” and aimed to answer the following questions in the scope of meaning in the use: What does the Surprise Egg afford in the context of usability and form?; what kinds of narratives do the participants develop in the process of making?; and, how do these narratives accompany or lead to the making of new artifacts?

To be used in the workshops, two different surprise egg brands are selected evenly according to their plastic capsule’s form. Additionally, for the up-cycling session for each workshop group, a kit of materials was prepared to support participants' attempts and inspire them for developing ideas and models. Therefore, the kits consisted of a variety of materials: Different types of ropes, piece of fabrics, EVA sheets, paperboards, balloons, plastic teacups, play dough, markers, scissors, glues, and etc. Moreover, some surprise egg toys’ were offered in a kit with empty plastic capsules.

3.1 Workshop I: A Day at the Nursing Home

3.1.1 Participants

The first group includes 8 male participants with an average age of 65 years, who did not have any prior experience with surprise eggs. They live at a nursing home, which has an additional rehabilitation centre. At this rehabilitation centre they usually work on hand crafts.

3.1.2 Procedure

In the first session in Workshop I, participants were asked to pick one surprise egg and unbox it.

The aim of Workshop I was observe how people who are not familiar with the surprise egg concept make sense of the semiotic references the product has while going through the steps of unboxing: Unwrapping the foil; ripping the chocolate shell in two or breaking it (can be simultaneous with unwrapping.); opening up the plastic capsule; and assembling the toy.

While the participants were completing the steps of unboxing, we observed interventions, which disrupted the surprise effect of the concept. Moreover, semi-structured interviews were conducted with each participant in every step, which reflect their reaction. At the end of the session, casual conversations were made about the toys that came out.

The second session started with a question to the participants by pointing the empty plastic capsules: “What can you do with this object?" In the following, we talked about their ideas.

A collective conversation took place and participants commented on each other's thoughts as well.

As a next step, participants were asked to choose one of the generated ideas and make a rough physical model of the object by utilizing the material kit. However, the majority of the participants chose to describe their ideas by talking instead of making.

3.2 Workshop II: A Day at the Elementary School

3.2.1 Participants

The second group contained 12 students in the third grade of an elementary school, who are eight to nine years old on average. All of them were familiar with the surprise egg concept. The workshop was conducted under the supervision of the class teacher at a studio-based class.

3.2.2 Procedure

For the unboxing session, the children were separated into two groups and asked to pick one surprise egg and unbox it. During this unboxing session, the children were asked to tell about their surprise egg experiences, with some stimulating questions, such as “What made you happy about the surprise egg?” or “Do you eat the chocolate first or do you want to get the toy before eating the chocolate?” As they are familiar with the surprise egg concept, they completed the unboxing session in one step and accomplished easily from unwrapping the foil to assembling the toy. At the end of the session, the participants were encouraged to talk about assembling toys.

In the following, the children were asked what they could do with empty plastic capsules and they were encouraged again for modelling their ideas. This process lasted for about 15-20 minutes. Then, participants presented their outcomes.

4. Findings & Discussion

4.1 Workshop I: A Day at the Nursing Home

4.1.1 On Recognition

Krippendorff (2006) describes recognition as “correctly identifying what something is, what it can be used for”. According to Krippendorff, the ability to recognize crucially depends on previous experiences with similar artifacts as recognition always is re-cognition; cognizing again. To get insight on how participants recognize the surprise egg, we aimed to understand how they make sense of how it works.

After the Surprise eggs were distributed to the participants, most of them firstly hesitated about how they could open the package, since they had no prior experience with the product. In this stage, some of them had difficulties in understanding and hesitated in unwrapping the foil. One of the participants, for instance, thought that unwrapping the foil was enough for unboxing it. Still, most of the participants went through "unwrapping the foil" and "ripping the chocolate shell" phases properly. Two of the participants had difficulties in opening the plastic capsule, as they had no recognition and tried to open the capsule from the hinged point (connecting line) by prying up with rasp. While one of them pointed the juncture (Figure 3), he expressed that "At first glance, it seems like it should be opened from the upper part. After I tried, I understood so, and it was directly opened from the middle of itself." In the light of this expression; we can say that the references on the product did not work as it intended.

Figure 3. Participant trying to open capsule from the hinged point (connecting line) by prying up with rasp.

Figure 4. A fish figure was out from one of the participant's egg.

At the assembly phase, most of the participants had difficulties in recognizing the toys and tried to figure them out for a while. One of the participants, got parts of a fish figure from the egg (Figure 4), and could not assemble the small parts of the toy at once. But he wanted to tell that he can understand that this is going to be a fish, indicating: "It is just a fish, nothing else." This statement initiated a conversation with the other participants on the fish when another participant came up and started to create a narrative about the toy: "It is a goldfish! It carries the other fish on its mouth to protect it from falling as a prey. This is how crocodiles do it."

Overall, we observed that participants make sense through *saying* rather than *doing*, since they had difficulties in recognizing and assembling the toys. Such difficulties basically destroyed the experience of surprise, and resulted in hesitation and uneasiness.

4.1.2 On Redefinition

In the up-cycling session, participants were addressed with a stimulating question: "What else can you do with this plastic capsule?". Following, they started to generate new narratives with the egg capsules. These more context dependent narratives focused on defining new specific functions. Participants usually had the tendency of redefining the egg capsule as a unit for "storage", where they could put their personal belongings, such as, pills, small coins, quarter gold coins, needles and buttons. Furthermore, one of the participants who was a former

fisherman, suggested that it could be used as floating pontoon for the fishing line. Additionally, two of the participants also asserted that they could make prayer beads or abacus by using modular capsules in this regard. Overall, we observed that past experiences and habits in daily life became were the main inputs in their new sense-making processes.

Participant whose plastic capsules had three holes underneath it; brought forward the "saltshaker" idea and acted out like sprinkling salt from the plastic capsule (Figure 5). At this point, we also interpreted it as building a part-whole metonymy.

Figure 5. Participants suggest the saltshaker idea and act out like sprinkle salt from the plastic capsule.

We observed that the participants tried to explore what the Surprise Egg capsule affords without much change and intervention. In this sense, they utilized a pragmatic approach, which was inspired by their daily life contexts and practices. Furthermore, generated new concepts, which are conveyed with narratives from adult-perspective, were focused on single-functional usage.

When asked to turn their ideas into three-dimensional models, the participants did not implement their formerly generated ideas. They shifted from *daily life context* and focused on *toy context*, aiming to address to a child's point of view. For instance, one of the participants started to create a playground from the EVA sheet, which was supplied in the kit. He, then,

started to pose various toys on it and asserted, “If I were a kid, I could create such a playground for fun” (Figure 6).

Figure 6. A playground created by one of the participants at the up-cycling session.

4.2 Workshop II: A Day at the Elementary School

4.2.1 On Recognition

Participants of Workshop II were quite familiar with the surprise egg context and they accomplished the steps from unwrapping the foil to assembling the toy quickly. When they opened up the plastic capsule, they expressed their excitement, such as, “Look! What we got!” and started assembling the toys. In the assembling phase, participants generally had quick

recognition on concepts and assembled the toys successfully. Most of them were not content with just assembling the toy and started to build narratives with and around them. For instance, one group got a specific bear figure (Figure 7). They associated this figure with the cartoon character *"Yogi bear and boo boo"* and then made changes on it by merging with a part of (balloon) a different surprise egg toy (Figure 7).

Figure 7. One group of the participants got a specific bear figure and made changes on it.

One of the participants got the figure toy named *creative smiley,* which has the part for creating patterns on paper (Figure 8). The participant figured out its function and assembled the parts properly. According to the instruction paper, this toy's main function was not for creating this kind of stamps. As it was designed, it was more likely for creating patterns on the paper through its holes. However, the participant wanted a piece of paper for creating a stamp by sandwiching the paper between the parts of figure. This was one of the early observations on participants' tendency in making conceptual changes starting from the unboxing session.

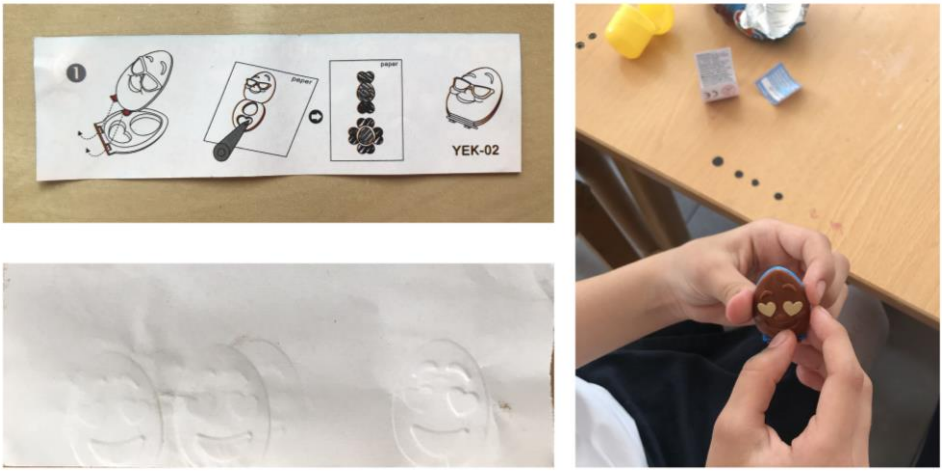

Figure 8. The figure toy's usage was changed over by participant and used as stamp instead of creating patterns.

In the unboxing session, all of the participants had a quick recognition of the toys and their concepts, and generally they did not have difficulties in assembling. It is hard to deduce about participants' abilities of decoding the semiotic references as they were already familiar with the concept and did the work almost *automatically*. Overall, we observed that participants of Workshop II experienced the surprise effect by going beyond from the surprise egg's offerings through creating new uses and narratives.

4.2.2 On Redefinition

In the up-cycling session, participants started telling their narratives. Most of them suggested to use plastic capsules for storing the *small things* as they expressed such as logo bricks, wristbands, lollipops, lovely beads, jewelry, tiny cars, and keys. Furthermore, one of the participants asserted that he could even store the shoes if it was big enough. Similar to the elderly, children created narratives in relation with their daily life and what the plastic capsules' materiality afforded them.

Afterwards, participants started creating new objects/ concepts through intervening plastic capsules by using different materials and methods. These interventions referred to making changes on plastic capsules by merging them with various materials or making changes by colouring it, and eventually turning it into a new functional object through redefining its meanings (Figure 9).

Figure 9. While participants generating new concepts with plastic capsules.

As many of, one of the participants made a surprise box as a gift for her friend's little sister. While she was presenting the concept, she expressed that, "I put some dough here to make the opening part more fun." and showed how it is opened from the hidden line (Figure 10).

Figure 10. Participant hides the opening line to got enhance the surprise effect.

One of the participants created a toy, which resembled Minion's characters. The toy figure was created from plastic capsule and was merged with a balloon (Figure 11). While indicating the knot point underneath the balloon, she expressed that, "The figure jumped on the balloon like in the cartoon. Look, the thing underneath the balloon helps for jumping!"

According to the outcomes of the workshop, it can be seen that participants redefined the toys by merging them together with other objects, colors and materials (Figure 10 and 11).

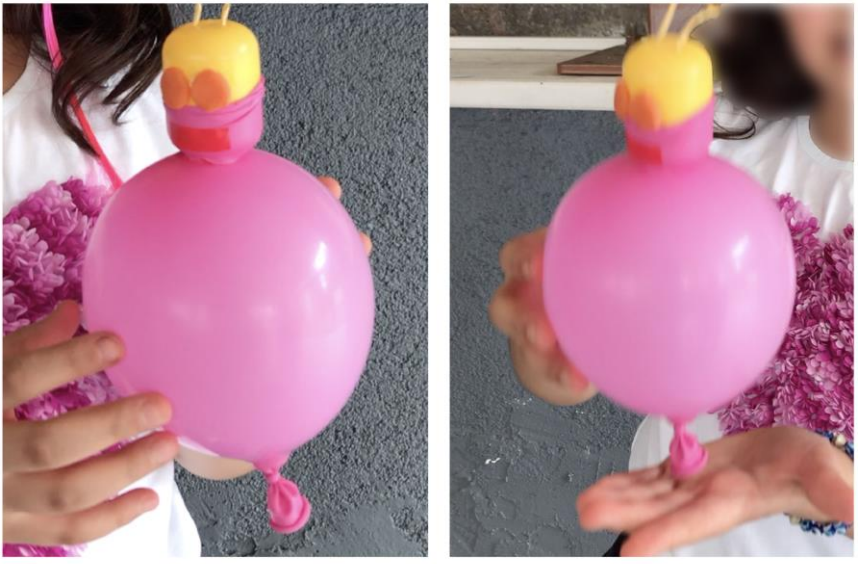

Figure 11. A toy character, which can jump around thanks to its elastic balloon body.

With a different approach, a participant created a toy, as a dinosaur figure by changing the plastic capsule by drawing on it. The participant explained while acting out the figure "It is like a dinosaur; we can play with it by opening and closing the mouth." (Figure 12)

According to the participant, this could also be used as a storage box for valuable things as well. He placed a cushion inside the capsule and indicated, "There is a beautiful place where we can store our valuable things."

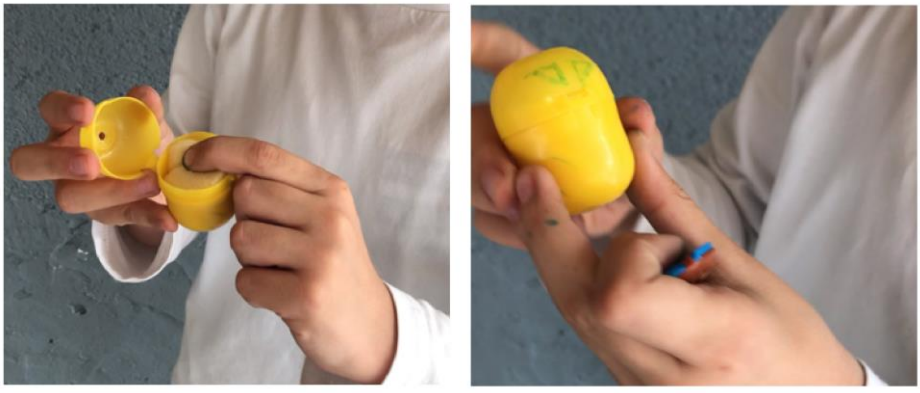

Figure 12. A multifunctional object from the plastic capsule.

In general, it is observed that both of the narratives and objects in redefinition process refer to multiple concepts, functions, and users. The participants were familiar with the surprise egg concept and also eager to redefine them benefiting and extending the capsules' affordances.

5. Conclusion

Within the scope of this study, we examined the surprise experience which is supposed to be the main element of the surprise egg concept and tried to figure out how the surprise experience changed in different layers. Furthermore, observing how new surprise effects are built up by participants helped us for understanding its usage in new sense-making processes. In this context, two different participant groups experienced different difficulties in various stages. Nonetheless, these difficulties provided us to take a new approach on “re-cognizing” and “re-defining” processes which are also related to familiarity with concepts and objects.

Designers and users cannot be presumed to see the world with the same eyes. It is also the same for different participants as their cognitive models and mythologies limit every participant (Krippendorff, 1989). At this point, starting to trace the concept of the surprise egg from a historical glance and finally integrating it with today’s narratives from different groups provided us with an initial insight how our participants made sense of this product.

As Krippendorff (2006) states children learn to see affordances by experiencing that what can they do and what the things can do for them. On the other side, most of the adults put their actions in practice without any need to reflect or decide what is next. Our findings from

this initial study support this approach: Participants who were not familiar with the surprise eggs at all, had difficulties in recognizing and thus making sense of it. In these situations, we observed that narrating on or around the object became an important part of experiencing and thus making sense of it. Therefore, stimulating narratives, which brought about meaningful worked well and encouraged new sense-making processes.

To conclude, this is a small-scale ongoing study through which we aim gaining insight on different processes of sense making, by utilizing a particular product, the surprise egg. Due to limitations based on time and resource restrictions, as well as the small sample size we cannot make a deeper analysis. However, we hope the methodology we followed can be applied for other products, participants, and cases for further research aiming at exploring sense-making processes of different participant groups.

The Design of Politics: Understanding the Arrest of Cesare Battisti Through the New Media Factor

Noemi Biasetton[a],
[a]Iuav University of Venice, School of Doctorate Studies, Curriculum of Design Sciences
Palazzo Badoer, San Polo 2468, 30125 Venice, Italy

Abstract | At present, populism is best understood as a combination of contextual issues (demand side) and the availability of successful parties (supply side). This article queries the impact of the new media factor as a third component for the fortune of contemporary populism, with the aim of clarifying how the features of new media communication can reflect or enhance the characteristics proper of populism. In order to do this, three aspects of the new media factor will be taken into account, hence the mediatization of politics, the process of disintermediation, and visual storytelling.
Specifically, the paper will analyze a controversial video posted on Facebook by the Minister of Justice Alfonso Bonafede in 2019, displaying the arrival at Ciampino Airport of the ex-terrorist Cesare Battisti. The latter will be used to explicit a coincidence of visual elements on digital media that can help political leaders better engage with their online audience, focusing on the assumptions that images can improve and facilitate the learning process, create identitarian spaces, and facilitate emotional involvement with the audience.

KEYWORDS | POPULISM, NEW MEDIA, VISUAL COMMUNICATION, CESARE BATTISTI

1. Introduction

In the last twenty years, many Western countries attended the rise of the so-called populist parties. Started out mostly as popular and/or local movements and small associations, many of them eventually shook the established political scene by gaining legislative seats, reaching government offices and hampering many accomplished traditional parties during the elections held in the last decade. On one hand, this phenomenon is being explored by scholars all over the world, reaching higher levels of sensitivity and specificity as more and more political events unfold. On the other, the word "populism" escalated to a point of no return in its popular use, acquiring an often-oversimplified significance.

In the scientific literature produced on the topic so far, it has long been a conventional procedure to begin any book or paper by stating that no one knows what populism is, and thus by noting the innate ambiguity of the term. A predictive episode with regard to this point occurred on May 1967 at the London School of Economics, where—among many academics—American historian Richard Hofstadter gave a keynote lecture titled *Everyone Is Talking About Populism, but No One Can Define It*. What was at the time a provocative title became later an actual presage, as in the last fifty years the term populism was discussed and enriched with more and more definitions given by scholars eager to bestow significance to this phenomenon.

However, this paper will not to take in consideration the many definitions given throughout the years to the term "populism" and will rather proceed to analyze the causes which allowed this phenomenon to spread, focusing on the communication modalities that co-occur with it.

2. Demand side of public opinion

Although the electoral fortunes of populist parties are open to multiple interpretations, according to almost all scholars the phenomenon of populism is articulated in demand and supply side factors, which are complementary to each other. The first factor mainly focuses on how economic insecurity affects populist support, whereas the second analyses the cultural attitudes adopted by populist parties—both left and right-wing—which allowed them to address social grievances and common concerns. Specifically, on the demand side there are two primary causal theories: the economic grievance model and the cultural backlash model. Often presented as opposing views, these two seek to provide answers to phenomena such as socialization, grievance formation, causal attribution and the formation of collective identity, which together constitute a breeding ground for the birth of populist parties.

The intuition behind economic grievance theory is that the economic fractures that were created and/or deepened by globalization generate potential public support for those movements which position themselves outside the political mainstream and oppose the rules dictated by the establishment (Rodrik, 2018). Specifically, according to this argument, economic insecurity and the ensuing perception of being forgotten fuels disdain for political

elites and institutions, reinforcing parties who bolster labor mobility and promulgate supranational governance (Andersen et al., 2017).
The second theory on the demand side is the cultural backlash thesis formulated by Ronald F. Inglehart and Pippa Norris (2016), which argues that the increasing accreditation of populist parties cannot be explained as a purely economic phenomenon but should be seen in large part as a reaction against progressive cultural change. Reactions to these developments, according to the experts, instigated a counter-revolutionary backlash among older generations and the less educated society classes which resulted in the decline of their livings standards and in their rejection of progressive values (Inglehart, 1997; 1999).
In short, if on one hand sectors once culturally prevailing in western Europe reacted angrily to the depletion of their privileges and status quo (the right-wing populist electorate), progressivists found their voice in left-wing populists' claims for inclusionary, more socio-economically inclined policies. Eventually, while examining these two theories about the demand side (the economic-inequality perspective and the cultural backlash thesis) researchers stated that

> "cultural values, combined with several social and demographic factors, provide the most consistent and parsimonious explanation for voting support for populist parties." (Inglehart & Norris, 2016, p. 4)

3. Supply side of party strategy

If demand side explanations are important to understand *why* populist parties emerged in the first place, supply side factors are valuable to figure out *how* the angry and disillusioned middle-class depicted in the previous paragraph was able to mobilize and eventually find a voice in populist parties across the Western world. The supply side of politics, in fact, applies when populist movements collect the quandaries and criticalities raised by common concerns, forge a narrative, and use that to activate political mobilization. Unnoticed (or maybe unwillingly spotted) by the so-called élite, many parties eventually pooled years of research into small communities' local vernacular, popular notions and national resentment, and mixed them with the most up-to-date tools for data analytics and advanced communication strategies borrowed from political worldwide masters (i.e. Vladimir Putin, Viktor Orbán and Donald Trump). The end result is they present a story that is meant to resonate with their base, the demand side, that says: here is *what* is happening, this is *why*, and *these* are the people who are doing this to you. According to Klandermans (2004), it is the process of mobilization that links demand and supply sides. And thus, because mobilization is the marketing mechanism of the social movement domain, the study of mobilization concerns such matters as the effectiveness of (persuasive) communication, the influence of social networks, the frames and ideologies movements stand for, and the constituents of identification they offer.

4. The new media factor

What has also been mentioned by scholars exploring the topic is that the common thread distinguishing left and right populism is their underlying ideologies. On the contrary, what binds these two types of politics together is their mobilization processes, which often involve social networks and powerful communication strategies. Indeed, as Surel (in Laclau, 2005, p. 176) claims:

> "against the idea according to which populism would represent a relatively stable and coherent trend, typical of the new radical right, we want to defend the idea that it is less of a political family than a dimension of the discursive and normative register adopted by political actors."

The introduction of a third explanatory component to unravel the intricate phenomenon of populism should not be intended here as the addition of a missing load-bearing element to previously examined theories. Nor should this component be looked at as a bonding agent between the demand-supply sides interpretations. But if we start from the assumption that politicians can be understood as strategic agents (Aslanidis, 2018, p. 1244), one cannot ignore that the advent over the past decades of new media completely revolutionized the key features and strategies adopted in the global political communication landscape.

The discursive strand in populist scholarship has been active at least since Ernesto Laclau's (1977) first take on populism. In his book *On Populist Reason* (2005), he defines populism as "a discursive strategy of constructing a political frontier dividing society into two camps and calling for the mobilization of the 'underdog' against 'those in power'." Most importantly, for Laclau populism is a form of mass politics that, far from threatening democracy, is rather a symptom of its liberating and radical horizons. Populism is thus for Laclau the latest link in a signifying chain that defines politics in terms of democratic practice, the hegemonic formation of group identities, and the play of language and discourse. According to him, populism is therefore not an ideology, and cannot be attributed to a specific programmatic content. A similar analysis of populism has also been taken into account by Taggart (2000), who associated the term populism with ambiguous definitions such as chameleon-like nature, essential impalpability or even conceptual slipperiness. To him, as well as to many other scholars (i.e. Mazzoleni et al., 2003), it is precisely thanks to this adaptive nature that populism can adjust to different contexts. For this reason, too, the distinctive nature of modern media and their capacity to affect the opinions and attitudes of mass audiences are key factors in the political arena (Mazzoleni, 2014). The contribution of such media to the rise of populist movements and parties is the research field that this paper wishes to tackle.

In order to do so, this section of the paper introduces a third causal and interpretative factor to help explain the rise of populism, called the new media factor, which will serve as an investigative query for the success of politicians' supply side through media communication. More specifically, the new media factor will center on the changes occurred in the new

realm of communication focusing on the processes of political mediatization, disintermediation, and visual storytelling.

4.1 Mediatization of politics

Throughout history, the term mediatization gained many different meanings in social and cultural research. According to Couldry and Hepp (2013, p. 197), the emergence of this concept can be dated back to the early twentieth century, with Ernst Manheim's (1933) postdoctoral thesis *The bearers of public opinion*, and later with the works of Jean Baudrillard (1981), Jürgen Habermas (1984) and Ulf Hannerz (1990). In their works, all authors refer to media in different manners, and attribute even more varied values to the concept of mediatization. Yet, the reason they all converge in Couldry and Hepp's list of mediatization theorists is their shared vision of mediatization as a way to decipher change. Specifically, they used mediatization as a concept to read the emergence of a particular medium in different historical socio-cultural processes. Far from being an established methodology, we can assume mediatization is more an investigative approach to media, "a meta process that consists of a changing everyday life, of changing identity constructions and social relations, of a changing economy, democracy and leisure, of a changing culture and society as a whole" (Krotz & Hepp, 2011).
In political communication, mediatization can be looked at as a long-term process of convergence between media-logic and political-logic occurred over the course of the last decades. This process happened mainly in two phases: firstly, with the media distancing from political power and becoming more and more marketed; secondly, with political actors strategically adapting to the logic followed by the media in order to gain visibility and attract voters (Esser, 2013). Eventually, since commercial media needed to "sell" political issues, they underwent a process of making those issues more understandable and interesting for the audience. This of course forced political actors to take into account media, who had to recalibrate and modulate their communication strategies to fit accordingly.

4.2 Disintermediation

The term "disintermediation" first appeared in Elihu Katz and Daniel Dayan's (1992) book *Media Events: The Live Broadcasting of History*. In the pages of the book, written in a period of absolute television-predominance over any other media, the authors name the presence of another television, different from the everyday kind, which they define as "a television of occasion" (Dayan & Katz, 1992). With this term, they refer to something other than the daily broadcasting of tv series or news. Some of the events reported as examples are the funerals of President Kennedy, the wedding of Charles and Diana, the fall of the Berlin wall in 1989, facts related to the Watergate scandal and many more. The intuition of Katz and Dayan, which first dealt with the innate ability of media to "spectacularize" events through media, posed some cornerstones for the future conceptualization of the process of disintermediation. On one hand, they showed how certain media have the power to clear a path for skillful public figures to talk over the heads of the "middlemen" who normally

mediate between leaders and their public, claiming that live broadcasting of media events "has redefined the relative power of organizers, intermediaries, broadcasters, and viewers, and the very essence of a public event" (Dayan & Katz, 1992, p. 217). On the other, they demonstrated how media events can work as disintermediation channels carrying the television public into the "sacred center" of society (Dayan & Katz, 1992, p. 89). Nowadays, the advent of new media extended the opportunity, for civilians as well as for politicians, to autonomously publish and spread daily events online, reaching an unprecedented level of life "spectacularisation". In the political realm, this meant for politicians to be able to independently manage their contents online, deflecting the usual mass-media "middlemen" mediation process.

4.3 Visual storytelling

In the past fifty years, studies in the psycho-cognitive field demonstrated that the attitude towards political leaders is regulated not only by the evaluation of proposed policies, but also and foremost by the emotional response to their non-verbal behavior (Masters & Sullivan, 1993; McHugo et al., 1985). At the same time, during the first half of the 1980s, philosophers and psychologists introduced for the first time the theoretical debate on narrative, acknowledging its centrality in the cognitive processes that lead individuals to the recognition of their self and/or of a specific community. These two factors, united with the explosion of the internet and the advance of communication technologies, created favorable conditions for the spreading of the "visual storytelling" model, today even further strengthened by digital media systems. By figuring as a sort of "immersion mechanism, a tool for profiling individuals, a technique for visualizing information", storytelling "establishes narrative systems that lead individuals to identify with models and to conform to protocols" (Salmon, 2017, pp 7-10).

Transplanted in political communication, visual storytelling demonstrated to be in the last decades an impeccable narration model and tool, with non-verbal language shaping largely the processes that feed the narrative of contemporary politics.

5. Visual populism

In *Understanding Media*, McLuhan (McLuhan, 1964, p. 80) correctly foresaw how advances in technology would have allowed rapid translation from one language to another. Indeed, as much as previous ones, the advent of new media brought a transformation in language, and subsequently also in culture, interactions among individuals, and modes of consciousness. They did so by adding to the spectrum of communication forms—not by destroying old means of communicating (Ong, 1977, pp. 82–91)—and by creating a new environment (Meyrowitz, 1986, p. 19) where the new medium is included in the previously set ones, adding new layers of understanding to the media matrix.
Although digital media comprise all digitized content that can be transmitted over the

internet or computer networks (which can include text, audio, video, and graphics), this research will specifically focus on visual imagery, both still and in motion. The reasoning behind this is that, due to the advent of new media and the consequent change of cultural practices related to information processing, politics has inexorably shifted onto a visual platform.

More specifically, this section of the paper questions the existence of visual populism, an expression coined to explicit a coincidence of visual elements on digital media that can help political leaders better engage with their audience on-line. Visual populism will be considered here as a proper communication mode, from which it derives a distinctive visual rhetoric which figures as a sort of algorithm for populist communication. In order to show how images on new media can foster the populist discourse, this theory will focus on three assumptions: that images can 1) improve and facilitate the learning process, 2) create vernacular, identitarian spaces, and 3) facilitate emotional involvement with the audience.

5.1 Visual learning

Since the 1960s, the role of images in the learning process has been largely explored by scholars of various fields, including those belonging to communication and political studies. In particular, starting from the 1990s, numerous researchers in this area started investigating how televised pictures, via mirror neurons, could foster a learning system able to engage the user's feelings towards the sender (Chaudhuri & Buck, 1995). In light of this, politics increasingly involved visual storytelling in communication processes through the use of media, which—besides ensuring a broader and more densely branched communication flow compared to traditional media—generate through the use of visual imagery a faster, distinctive and direct kind of learning (Tversky, 2019, p. 242).

Audio-visual communication, also, is capable of generating an accurate representation of non-familiar people and objects (Graber, 2001, p. 19), thus allowing leaders to provide their followers information on socio-political issues they might have never heard of or may have encountered only in purely verbal contexts. Political actors who make use of visual technologies to communicate with their audience have therefore the power to construct reality in a specific way, and even to frame particular situations by telling a story with the help of visual aids.

5.2 "Framing" and the process of identification

The employment of audio-visual systems by political leaders is useful not only to instruct their audience about political and social issues, but also to create a vernacular shared idiom which is unique and recognizable from the community of one particular party. Through visuals, indeed, leaders have the possibility to create virtual identitarian places, where social media become a bridge able to connect the imaginative with the real.

On the subject of identity and politics, the contribution of George Lakoff is of paramount importance. Specifically, in his *Don't think of an elephant!* (2004) the American cognitive linguist and philosopher introduced the concept of "frame", defining it as a set of

interrelated ideas which nonetheless belong to the same subject and to an unequivocal perspective on it. If effective, the frame works as a sort of setting wherein ideas assume an organizational shape, becoming persuasive when language evokes them. Through this method of cognitive assonance, the leader conveys both with words and visual representation a collective imaginary which becomes a sort of genetic heritage of social belonging. This way, the social media pages of leaders become environments able to feed and direct the "common feeling" of their followers, clarifying who is part of one community (defining the "us") and who oppose to it (identifying "them").

5.3 Emotional involvement

As we have seen so far, audiovisual systems allow anyone who use them to provide explanations on complex socio-political topics and to forge a repertoire of signs shared within a specific community. Compared to verbal communication, images are processed faster, categorized more efficiently and better remembered (Grabe & Bucy, 2009, p. 12). In fact, while in verbal communication affective stimuli have to be imagined, in visual communication they can be synesthetically, sensually, and kinesthetically perceived, triggering a stronger, more direct and faster response in the receiver. Furthermore, affective processes elaborated in the subcortex nourish conscious experiences that are complex and abstract, turning them into vivid and polysemic signs (Coëgnarts & Kravanja, 2012). Through a sort of Gestalt composed of formal aspects (such as color, movement, pacing, camera angle, etc.), objects and subjects, images carry signals that are later transformed in affective impulses able to increase the effectiveness of identification and learning processes.

6. Case study: "The story of a day we will hardly forget!"

On the 14th of January 2019, the Minister of Justice Alfonso Bonafede (representative of Five Star Movement) posted a video on his Facebook page showing the arrival of Cesare Battisti in Rome titled "Il racconto di una giornata che difficilmente dimenticheremo!" (in english: "The story of a day we will hardly forget!"). Battisti was a member of the Armed Proletarians for Communism[1] (PAC) and had been sentenced in 1979 to twelve and a half years of detention to serve out multiple life sentences for murders during the "Years of Lead". In 1981, after only two years, he successfully escaped from prison and spent nearly four decades on the run, with granted asylum in France, Mexico and eventually Brazil. His extradition here was halted by former president Luiz Inácio Lula da Silva and generated diplomatic tension between the two countries ever since. Battisti was eventually arrested on January 12th, 2019 in Santa Cruz de La Sierra (Bolivia) in an international police operation and brought back to Rome Ciampino airport on an Italian-flagged Falcon 900 plane.

[1] Armed Proletarians for Communism (Proletari Armati per il Comunismo) was an Italian far-left terrorist group founded during the "Years of Lead".

The video posted by Bonafede, which was watched over 350 thousand times in the twenty-four hours after its publication, is interesting for the reasoning of this paper under many levels. On one hand, the processes that led minister Bonafede have that video produced and spread resonate with the three characteristics of the new media factor taken into account in the third paragraph. To begin with, the event of Battisti's arrival in Rome elicited a great stir on social media, where the case lived and escalated quite rapidly through the posts of many international political personalities. Indeed, besides the posts published on Twitter by Italian politicians, the arrival of Battisti in Italy was even announced by Eduardo Bolsonaro, son of the newly elected president of Brazil Jair Bolsonaro, who responded to a tweet by Salvini with the words "Brazil is no longer a land of bandits. The 'small gift' is coming". (Figure 1) The video is thus the result of the underlying processes of politics mediatization, since politicians—in order to "sell" political issues—undergo a process of making those issues more understandable and interesting for the audience. The act of defining Cesare Battisti a "gift" is used here as a conceptual metaphor (see Lakoff, 2006), and serves as a conceptual tool for structuring, restructuring or even create reality. After that, by considering the arrival of Battisti a "media event"—as defined by Katz and Dayan (1992)—the choice of the medium onto which the video was posted is as obvious as reasonable. In fact, by using Facebook as the preferred sharing platform, Bonafede was able to autonomously publish and spread the product online, reaching an actually unprecedented level of spectacularisation and at the same time deflecting the traditional mass-media "middlemen" mediation process. With regard to the narrative choice, this episode unveils the "storytelling machine" (Salmon, 2017) with the boundaries between fiction and non-fiction growing increasingly fragile.

Figure 1. Eduardo Bolsonaro's tweet on January 13, 2019.

Dismembered in five sequences and twenty different shots, the video depicts different moments of Battisti's arrival in Rome together with his departure towards prison. To play it are three actants: the "villain" (Cesare Battisti), the "hero" (penitentiary police, who is also responsible for the production of the video) and the "sender" (Alfonso Bonafede).
In the first three seconds, which serve as an introduction, Cesare Battisti is presented through a series of five black and white pictures with a camera shutter clicking sound. These initial frames are of paramount importance because they showcase the "villain", which is going to be seen shortly after in his journey towards prison. Furthermore, the sequence composed by a series of black and white pictures with the shutter sound is a classic montage used in television fiction to frame either wanted persons or spied ones (for example, the same sequence settings resemble in an almost identical fashion the end of the sixth episode of The Sopranos first season, where uncle Tony is captured with a photo-finish by an FBI agent at a dinner party as the new boss). (Figure 2)

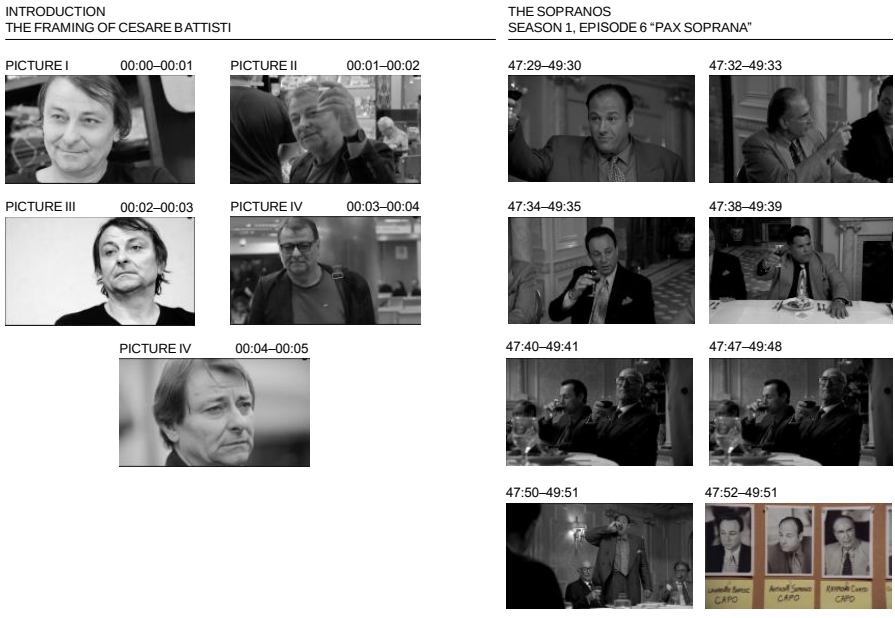

Figure 2. Introduction of Battisti's video compared with a famous sequence from the TV show "The Sopranos" (1999).

In the following five sequences, on the notes of *Comment Te Dire* by French artist Bertysolo, the heroes and the sender showcase their conquest (the capture of the villain), thus dramatizing an institutional event aimed at radically transforming the public opinion on a specific and major issue. (Figure 3, Figure 4) Besides being useful for the identification of the "villain", the video is very effective in creating a visual story which simultaneously frames a current event (Battisti arriving in Rome after his capture) and gives the viewer a key to read

the whole story: Battisti's forty years on the run, the diplomatic issues with the countries that granted him asylum, the satisfaction of the victims' families finally getting justice, and more. Indeed, by staging the detainee as subordinate to the authorities, the sender of this message is expressing a clear position on the subject yet without making use of verbal communication. In the video, both structure and content have the ability to elicit responses which direct attention to specific features of the message, which is expressed through the rise of music in key moments, with gestures of police officers and the interactions between them and Bonafede.

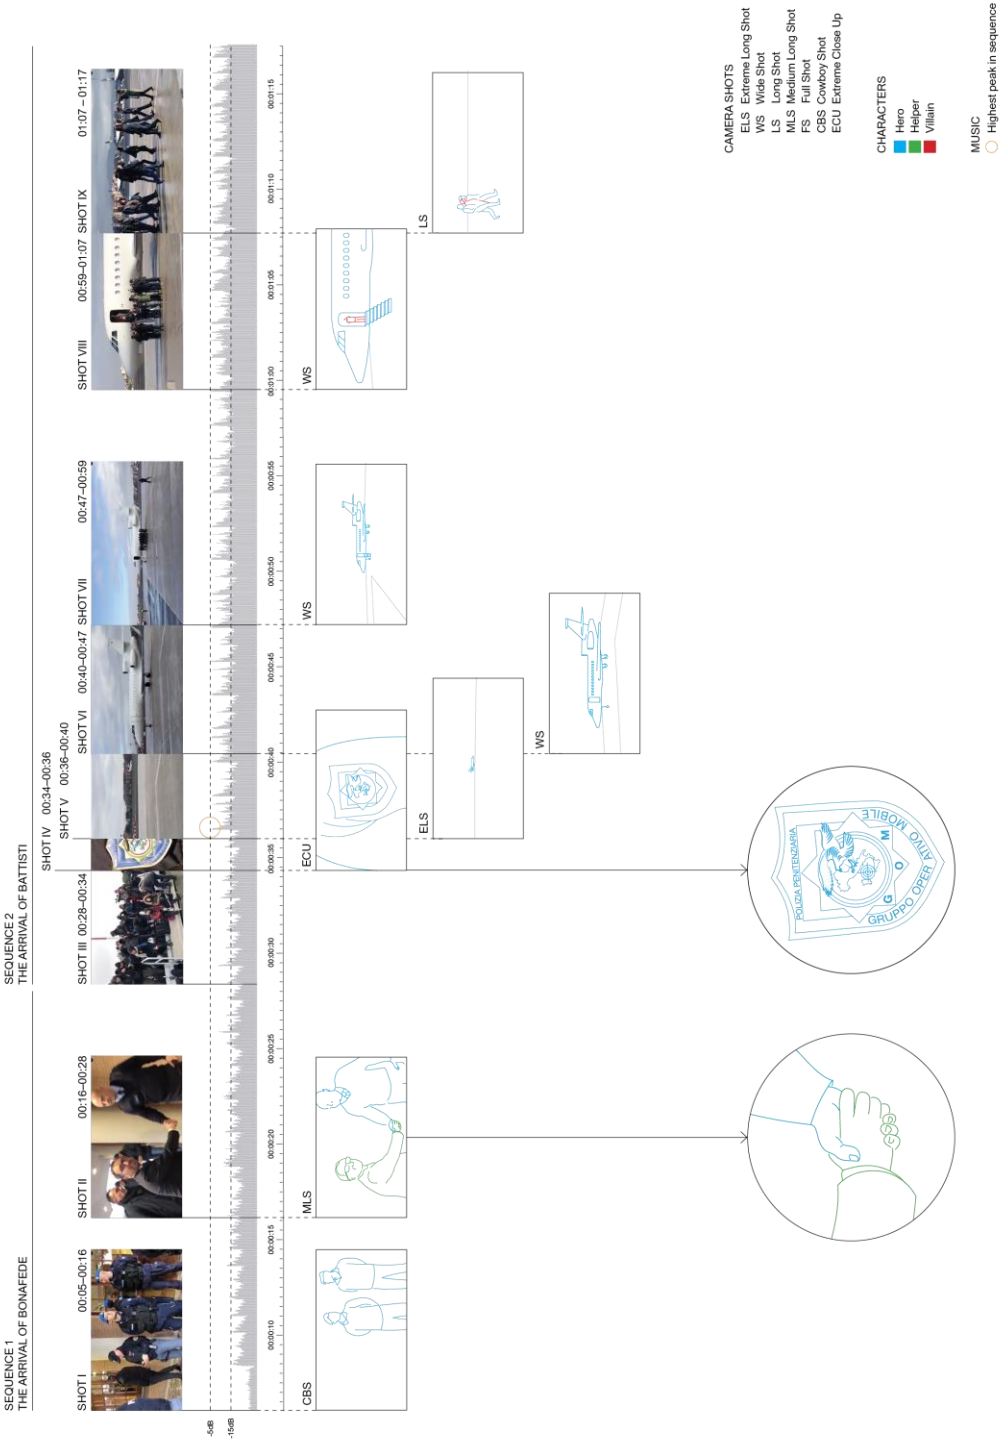
The last crucial aspect of this event is that the video became the subject of a great media debate, triggering many outraged judicial authorities who defined the posting of such video "one of the most shameful and grotesque pages of our republican history"[2] (*Unione Camere Penali Italiane*). It was indeed the *Unione delle Camere penali* who, on the 15th of January 2019, published a public statement where the lawyers pointed out the violation of the article 114 subparagraph 6-bis of the Code of Criminal Procedure, which states that any publication of people deprived of their liberty is strictly forbidden unless consented.[3] Also, according to Mauro Palma (National Guarantor of the rights of persons detained or deprived of their liberty) the staging of Battisti's arrival was a clear violation of article 42-bis subparagraph 4 of the Penitentiary Law, according to which detainees should be protected from public's curiosity and/or publicity during the process of accompaniment from one place to another. Before having the video removed on the 17th of January (three days after its publication), Palma on a public statement eventually warned about "sentences and images that aim to reach consensus through a language stranger to that of Constitution and that end up consolidating a culture of social disruption and tension."[4]

2 In Italian: "una pagina tra le più vergognose e grottesche della nostra storia repubblicana." The translation is curated by the author.

3 In Italian: "È vietata la pubblicazione dell'immagine di persona privata della libertà personale ripresa mentre la stessa si trova sottoposta all'uso di manette ai polsi ovvero ad altro mezzo di coercizione fisica, salvo che la persona vi consenta." Divieto di pubblicazione di atti e di immagini, Articolo 114 Codice di procedura penale (D.P.R. 22 settembre 1988, n. 477). The translation is curated by the author.

4 In Italian: "frasi e immagini che puntano ad acquisire consenso attraverso un linguaggio estraneo a quello della Costituzione e finiscono per consolidare una cultura di disgregazione sociale e di tensione". Retreived from www.garantenazionaleprivatiliberta.it The translation is curated by the author.

Figure 3. Sequences analysis (01-02).



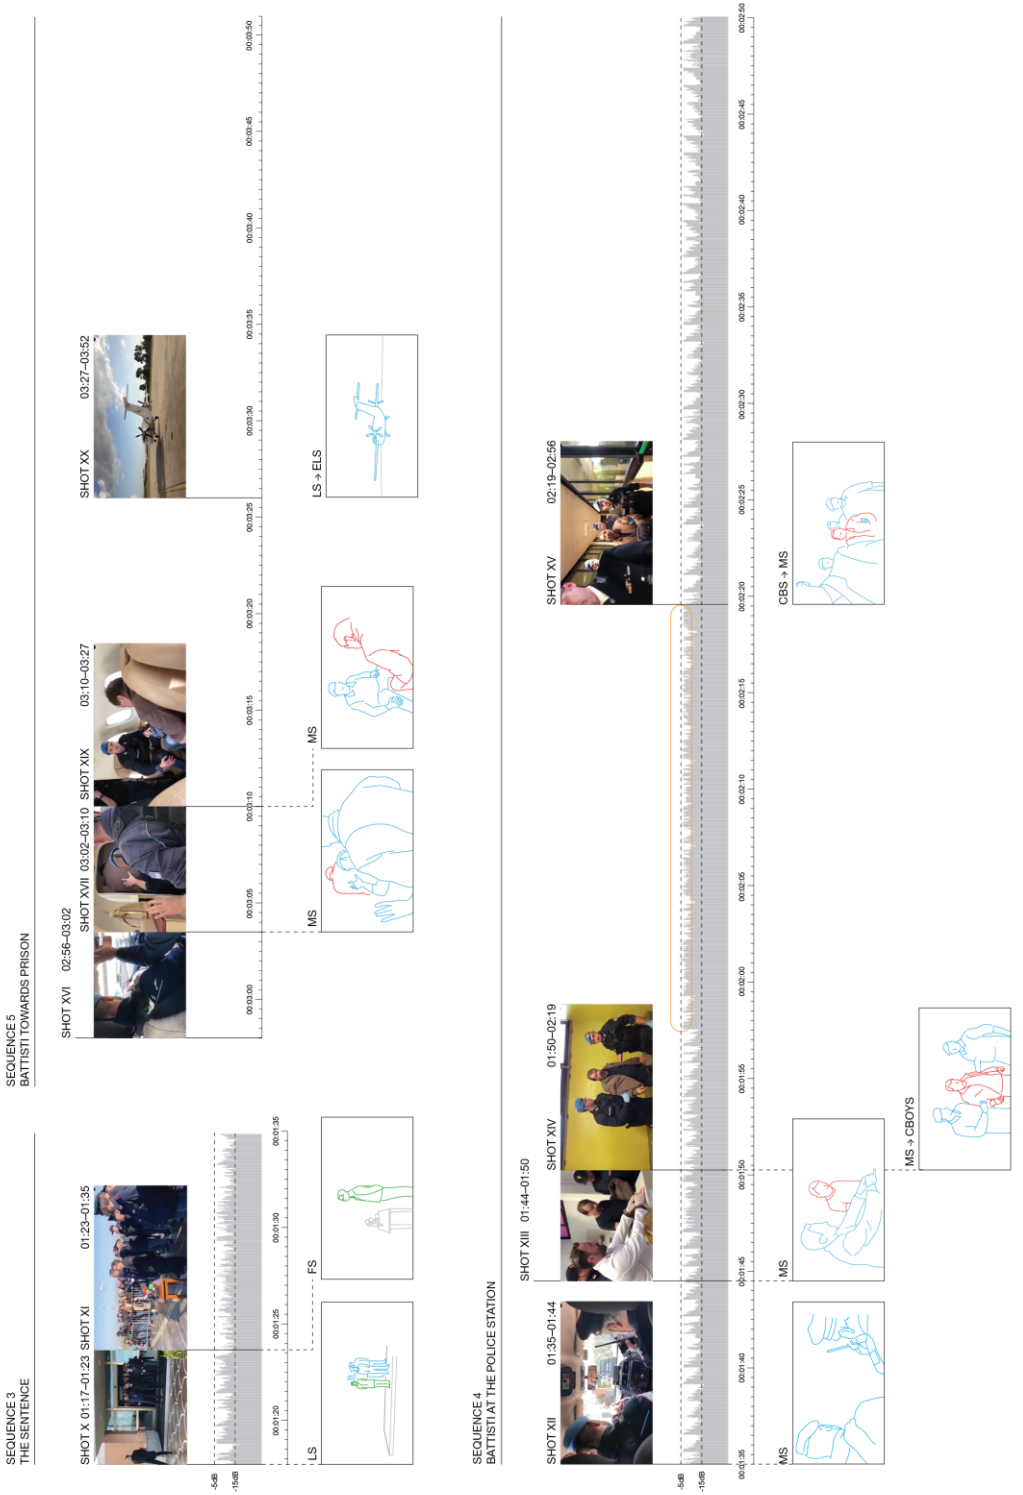


Figure 4. Sequences analysis (03-04-05).

7. Conclusion

As politics has increasingly become intertwined with the power of media to visually display reality, people's perception of politic is based to a large extent on the contents shared by politicians on social platforms. As seen previously with the case study of Battisti's video, visual populism shows how politicians can frame and construct reality in a specific way, by telling a story which is meant to resonate with the electorate with the help of visual aids. The case study also exemplifies how audio-visuals products shared on new media can enter in the public debate, overshadowing news reports by traditional media and dictating new standards of newsworthiness. Lastly, the case shows how images can elicit a juridical debate—which would have been unthinkable just a few decades ago—thus reinforcing the idea that images can do harm, whether intentionally or not.

"The Enlightenment of the Contemporary Transformation of Chinese Traditional Visual Space Perception on Cultural Sustainability design"

Jixiang Jiang*[a], Dong Tao[b],

[a]Jixiang Jiang
[b]Dong Tao
*Jixiang.jiang@polimi.it

Abstract | "Visual perception," which reflects a very complex social-cultural phenomenon. How humans percept the surrounding world through vision, also how humans express or "transfer" the visual impression into the creation of artifacts such as painting and space, is the key to creating the understanding bridge between tradition and modern, western and eastern. To achieve this research goal, author explores the commonalities between Chinese and Western visual-spatial expressions through the analogy between traditional Chinese landscape painting and Western modern art, and explores different ways of transformation the traditional visual-spatial artifact codes by exploring the common visual themes maintained between traditional landscape painting and Chinese contemporary art, so as to explore the cross-cultural elements of traditional Chinese landscape painting, which is a traditional symbolic language system, and to guide the practice of design during the process of transformation from traditional to modern. The visual identity design of Art & Media College, Tongji University, was created during this process of researching. This practical design project allows people with different cultural backgrounds to sustainably, understandably and acceptably attend to, this practical project, a sustainable transformation about design approach and tools have been built up.

KEYWORDS | VISUAL IDENTITY DESIGN, VISUAL PERCEPTION , TRANS-CULTURAL UNDERSTANDING,CULTURAL SUSTAINABLE DESIGN , EAST ASIAN ART HISTORY

1. Culture is the Source of the Sustainable Development of Design

It's the sustainable development of culture the core of the Sustainable Development Goals (SDGs) stated by the United Nations. If the SDGs take economy, society and environment as the three pillars, then culture and creativity make important contributions laterally to each pillar. “Its culture shapes the way you see the world, its language informs the way you think, its customs structure you as a social being” (Willis,2006)Culture is also a constant source of the development of design, which, on the one hand, originates from human needs and the crises and opportunities that exist in human development; on the other hand, it also exists in the understanding, interpretation, and reflection of the world by human beings. Therefore, "Design is more pervasive and profound than that generally recognized by designers, cultural theorists, philosophers, or laypeople." The sustainable development of culture brought by design is to form a consensus with an international identity by creating keywords and key propositions that belong to contemporary Chinese culture in a global coordinate system, which are transformed into theoretical basis that can be used for modern design, and integrated into the modern living system under the impetus of design practice.

2.Cultural language is the Source of Diversified Development of Design

"I've always been a student of culture-I've been thinking about the importance of culture for product design, and experimenting with cultural thinking and tracking or exploring ways to influence culture. I strongly believe the way that culture designs us, so I recommend taking cultural thinking as a framework to assist us in design. Cultural thinking is a way of actively observing the behaviour of design, its impact on our culture, and the way we think about improving human interaction with others in society. While understanding, understanding itself reshapes our perception in turn. In the process of the transformation of design discourse, it is also the recreation of design culture." (Madray, 2017)

Compared with the profound human civilization, the history of contemporary design is not long, and its development time in China is even shorter. However, the perception of the same thing by people in different regions has differences in terms of cultural thinking and cognitive understanding, the relationship between design and each cultural matrix is inextricably linked. Therefore, the diversity of culture and language also provides more possibilities for the development of design.

The design community in China is currently in the transformation stage (Lou Yongqi, 2015), in universities, this is reflected in the following two aspects, I), it introduces, studies and learns from the design education system of western universities to cover and integrate China's design education practice and the innovation strategy system of enterprises -

universities - government trinity service design, inclusive design, strategic design, social innovation and other design frontier areas from point to whole; ii) "Our thoughts shape our spaces and shape our tools, our tools and space return the favour-as Steven Johnson tells us" (Madray, 2017), While adapting to Western design theories and tools, Chinese design is also constantly looking back to sort out the long historical traditions of the past. Interdisciplinary research, such as exploring the inspiration of modern design from the cultural foundation according to the characteristics of regional culture in combination with Sociology, Art History, and Anthropology, the explorer for example: Wang Xin and Wang Shu from Chinese Academy of Fine Arts, Ji Tie from Hunan University, et al. Exploring design theories that are suitable for one's own cultural characteristics in the process of development is not only an attempt to strengthen China's discourse power in international design culture, so as to make its time-honoured and modern civilization value to spread more widely, and to achieve cultural renaissance, but also a cultural reflection on the difficulty of the common design to deal with the localized development.

3.The Carrier of Visual Perception – Chinese Traditional Landscape Painting

Chinese traditional landscape painting, as an abstract artistic expression of conscious thinking, is a good starting point for studying visual perception.

Chinese traditional painting has always been different from traditional Western one, in both development and objectives. The trend of modern design theory is going towards interdisciplinary and cross-domain development. Hence, the exploration of the traditional culture in order to trace back the source of a theoretical guidance of Chinese design development seems to be the new direction along which moving forward: a perspective that will help in shaping a modern and inclusive language of Chinese design and will offer a clear understanding of the different cultural background.

The subject of this paper is Chinese traditional landscape painting, which acts as a carrier of visual space. In the process of painting, people are also repeatedly "designing" to confirm the thinking pattern in their hearts. "Visual perception" is a very complicated social and cultural phenomenon. How to "see" and how to express "what you see" are social or cultural discourse acts. There are various forms of "seeing", and the socio-cultural connotations they include are also complex and diverse. Vision is defined as a kind of "thinking" by Rudolf Arnheim in his book "Visual Thinking: Psychology of Aesthetic Intuition"; In Gestalt psychology, visual perception is the thinking that exists in vision; Susanne K.Langer, the representative of symbol aesthetics, also stated that what we see with our eyes is a form of the joint construction of sensory and intellectual organs.

4. “Kan[seeing]” and “Guan[observing]”

4.1 Thresholds of “Kan[seeing]” and “Guan[observing]”

The author analyzed the connotations of the following verbs related to "seeing" in Chinese traditional painting theory in combination with the context of ancient Chinese writing:

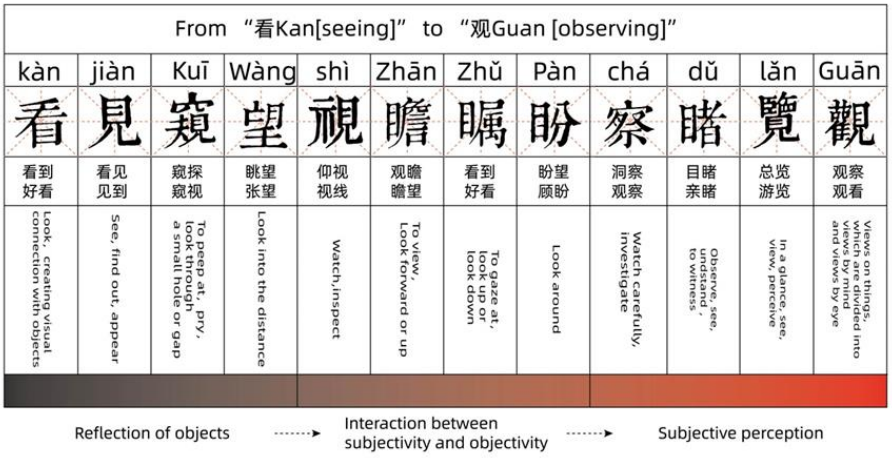

Table 1. Thresholds of “Kan[seeing]” and “Guan[observing]” [_DCs Table title].

Among them, the character "*Guan*" is obviously more in line with the deep definition of vision given by Arnheim and Susanne K.Langer .

It's originated from Xi Ci 系辞 (I) of I Ching Yi jing 易经(Book of Changes): "Looking up to observe the phenomenons in the sky, looking down to find out the laws of the Earth."

“The earliest understanding of the character *“Guan”* can be found in the I Ching .

It was stated in “Xiang 象” that “Winds moving above the Earth, *Guan*.” *Guan* are formed by the two trigrams representing one the Earth and the other Wind moving above it. “According to this explanation, both the human experience of observing the outside world and the ability to perceive it in its unity are involved: an ontological approach that connects and combines the human heart-mind experience with Nature – i.e. the Tao Dao 道, the origin of all things.”

Zong Bing 宗炳 of the Southern Dynasties said "Settle the hearts to view the Tao", as a mode of thinking that people use to experience the Great Law of universe -Tao, "*Guan*" is a verb that can be implemented concretely, and the object of "*Guan*" is the Tao. The specific creation of a landscape painting is carried out under the guidance of the thinking mode of "*Guan*", and a thinking system of visual perception completely different from that of the West has been formed.

4.2 Object of “Guan” - the Source of the Physical Images

"*Guan*" is a kind of structural "seeing". It has cultural presuppositions, among which one of the important points is the concept of "source of physical image". This also leads to the unique characteristics of Chinese landscape paintings, such as containing four-dimensional space-time in two-dimensional pictures. The reason is that the concept of "*Guan*" predestined that Chinese landscape painters do not paint what they see or what they know, but their feelings and understandings of "the source of physical images" in the world they live in. Such feelings are not a matter of being inside, but a sense of being outside.

Xu Fuguan stated in his "Spirit of Chinese Arts" that "the so-called Source of Physical Image is the nature of what physical matters are derived from, however, the nature cannot be separated from the form" and "Only when painting can express the nature of things, can it be said 'getting the truth of things'"（Xu，2001）. The above statements show that everything has common sense, and only artworks that can express the essence of nature can reflect the Tao behind the physical images. Contemporary scholar Wei Bin said in his "Explanations on the Theory of Paintings of Tang Dynasty" that "The image of landscapes, the momentum coexist with each other (Explanation: The charm and form of landscape painting complement each other)" , "Not the landscape having this momentum, but the image of the landscape reflected in my heart which move with the movement of the heart, so it is said that the spirit and form coexist with each other."(Wei,2007). It is this common sense that maps the landscape schema in the hearts of human beings, and thus arouses their perception of nature.

The source of the physical image refers to the ins and outs thereof. Only by observing the details of the things, and then the painting can get the truth of creature. People in the Song Dynasty believed that knowledge is acquired through investigating things to the utmost, and its nature should be explored by understanding the principles of things. "Clarifying the source of physical image" actually inspired the concept of "Shang Li (Advocating rationality)" in paintings of the Song Dynasty. It is also the beginning of our research on the interpretation of art works from the level of the schema of Chinese classical landscape paintings.

Generally speaking, Jing Hao's "source of physical image" is actually a reconstruction of the "common sense" of the nature that must be grasped in the space theory and creation of Chinese classical landscape painting, that is, an interpretation of the Chinese landscape painting pattern. The "source of physical image" should be understood as the essential existence of the original, inherent, natural, but also interdependent development of everything according to its own internal laws.

We can summarise the visual principles of this idea of pursuing ‘the source of objects and images’ in three main points（Accolla, A., & Jiang, J.2019）:

1. The importance of orientation The relationship between distance, direction, and position is constant and objective, regardless the subject’ s position.
2. The importance of the original proportion As advocated in the Yi Jing, the integration of men into Nature should not affect or interfere.
3. the natural state of objects and, therefore, respect the original proportions of the world.
4. The understanding of visual laws The Yi Jing also expresses that when the objective conditions of the objective world change, people’ s perception remain unaltered to a certain extent, since there is a tendency to perceive familiar objects as unaltered in shape, size, colour, brightness and so on, despite the stimuli changes may involve, i.e. the principle of perceptual constancy.

4.3 The Organizational Features of the Space Art Elements of Landscape Painting under the Influence of "Source of Physical Image"

Through the exploration of "*guan*", the inherent "schema" is gradually abandoned, and this philosophical proposition, which has the characteristics of traditional Chinese cultural thinking and the common characteristics of modernity and human visual perception, is translated into the concept and method of visual space that can be used and understood by modern design.

1. Lines - the Carrier of Art Life

In the landscape paintings after the Song Dynasty in China and the history of modern western art, the liberation and expression of lines occupied an important position. Most of the landscape paintings in the Song Dynasty were painted on scrolls, with more smudges and strong naturalism. In the Yuan Dynasty, artistic elements, such as lines, began to play a key role in painting expressions as pure art forms separated from natural objects and images. How did lines in landscape painting represent space-time? How were art elements such as points, lines and planes used in the expression of physical images? Through analysis, we find that in the plot of Huang Gongwang's Dwelling in the Fuchun Mountains(Figure 1-1), the painting dominated by line expressions:

As a carrier of natural objects and images and space-time, in the composition of mountains in this painting, it did not emphasize the quantitative change to qualitative change of artistic elements, such as points to form lines, or lines to form planes, but highlighted the expressive force of lines as an art element, and the relationship between various elements was dominated by the expressiveness of the lines.

The slight intervention of dots enhances the richness and naturalness of line transition. The combination of lines is a metaphor for the generation of planes. There is no very close interweaving between lines, but there are spaces. The relationship of "Being and Not-being

grow out of one another" between lines, and the wet and dry shades of lines that are achieved through brush and ink, continuously promotes the continuous extension of planes (Figure 1-3). However, there is no line arrangement similar to that in western sketches, that is, the mechanical superposition and intersection of lines to produce planes which are often used to express a relatively fixed momentary image, but are difficult to achieve extension in space and time.

Driven by these two kinds of relationships, the kinetic energy of visual shift and relationship change is generated, which organically promotes the extension of time and space. This relationship is particularly obvious in comparison with the works of Chinese contemporary artist Zhou Jie(Figure 1-2) . For the same motif, the tranquil landscapes, Huang Gongwang and Zhou Jie adopted very different treatment methods. Zhou Jie used long scroll painting composition, and highlighted the art element of lines , but the way of expression was deeply influenced by western painting consciousness(Figure 1-4), the lines were interweaved to express volume (space), hence the performance of the lines themselves depended on the generation of the volume image, making it difficult for the lines to be independent as an art element, and the landscapes they constructed was a three-dimensional miniature model, the space was confined in a quiet atmosphere and couldn't be extended freely, nor did it have the mental conception produced by the Gestalt completion effect.

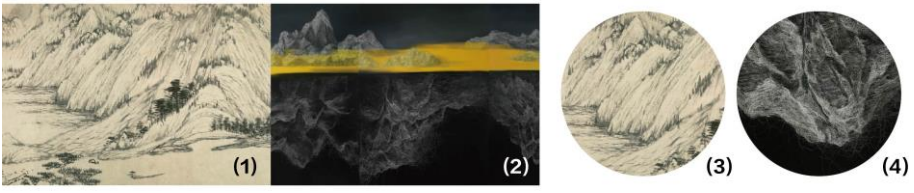

Figure 1. (1). (3).Huang gongwang 黄公望(1269－1354): Fu chun shan ju tu(富春山居图)，(3).(4)Zhou Jie 周杰：Where Are We Heading To? No.9 (artplusshanghai.com).

2. Contour and Mass - Drawing Game

Cezanne used dark lines to outline the still life, making the still life look clear and solid, and the unique role of the contours began to show. "Cubism" inherited the tradition of Cezanne's rational analysis of the structure of paintings, and tried to form a painterly space and physical structure through the decomposition and reconstruction of space and physical images to reduce the descriptive and expressive nature of the work, so as to organize a geometric structural beauty. In this process, a drawing language of "simultaneous vision" became the most important transformation of Cubism, which represented different visual images of the same object from various angles through the observation of multiple perspectives at different viewpoints. In essence, it is the deconstruction and analysis of objects (Figure 2-1).

Contours, as a sign of the transition of space, are essentially external lines to emphasize and distinguish between spaces and forms. In cubist paintings, contours are unfolded from a three-dimensional space and spread in a two-dimensional space. This is the key to realize the transition from a three-dimensional space to a two-dimensional space with characteristics of four-dimensional space-time. The role of contour is fully exerted.

In terms of the operating concept of space-time expression, cubism and Chinese landscape painting have a great degree of similarity in the composition method, but there is a problem for cubism in the expression of a four-dimensional space - the fragmentation of the image and the feeling of viewing (Figure 2-2), while Chinese landscape painting has a consistent sense of tranquility and nature without losing the narrative content. The key is that the two civilizations have different cultural origins, values and art languages (Figure 2-3,2-6).

On this issue, Purism is against Cubism's eliminating the integrity of the objects by emphasizing the change of viewpoints, hoping to further abandon the overly complicated structural details and show geometric characteristics. Purist painting also deals with the image of things by means of superimposing side contours on orthographic projection. It inherits the multi-view observation method of cubism and superimposes two different viewpoints. This processing method, has the following two effects: on the one hand, the spatial depth of the picture is compressed, presenting the expressive characteristics of shallow space; on the other hand, because the contours of all objects are very clear and interdependent, the picture maintains a strict order. Purist painting finally combines the visual image in reality with the cubist observation method of multi-perspective and different viewpoints, thus creating a new "stereoscopic" "reality".

China has a complete system of solutions to the problem, of which the two important elements are the processing of contours and the use of masses (Figure 2-4,2-5). In the Ming Dynasty, especially in the middle and late periods, the direction of art changed. The development of commerce and the civic life have enriched material civilization, so the scholar-officials did not suffer from the depression and lack of desire like those in the Yuan Dynasty; the interpersonal relationship and the relationship between man and nature also became increasingly prosperous and complicated, and the landscape painting art shifted from pure self-expression to a paradigm with more space-time experience and gamification, which required the landscape painters to have the ability to solve changing and diversified space-time. As a result, the potential of contours and masses was explored. As a single form, the mountain boundary is bound to have an end, and the perspective sense of "everything looks big in the near and small in the distance" generated by human visual perception is inevitable even in landscape paintings. In the picture below, we find that the high-altitude composition of paintings in the Song and Yuan Dynasties had been transformed into a image in depth with a space-time narration effect (Figure 2-8). For the specific composition of mountain paintings, the shape of the mountain body was no longer majestic and complete, the boundary turning points were shattered by fragmented combinations of rocks and stones or organic contours, so as to avoid the spatial isolation caused by human visual

perspective in all spatial nodes. In this way, the extension of the space was maintained and it was also in line with the practical experience of people traveling in the mountains(Figure 2-7).

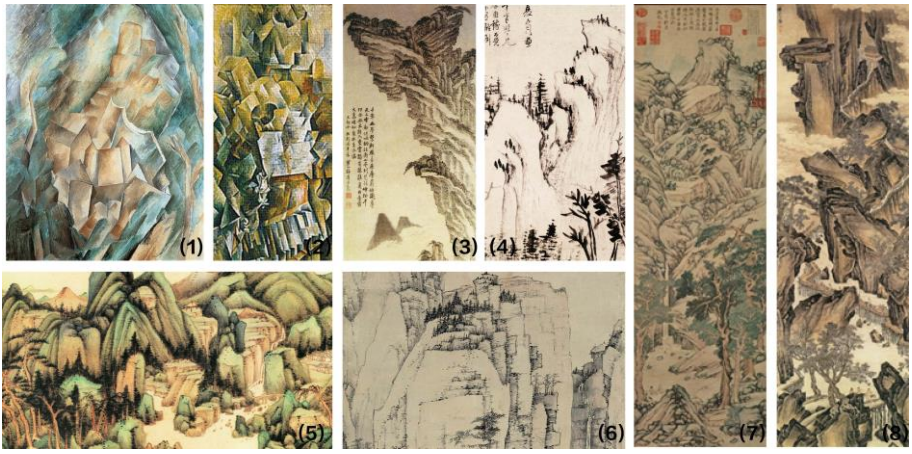

Figure 2.Representative work of (1)/(2)G.Braque(1882-1963).(3)Mei Qing 梅清(1624-1697).(4)Wang Zhirui 王之瑞(?-1660).(5).Wang Jian 王鉴(1598-1677).(6)Hong Ren 弘仁 (1610-1664).(7).Wen Zhengming 文征明(1470-1559).(8).Xie Shichen 谢时臣(1487—1567).

3. Geometry - Gestalt Completion

The overall style of Chinese painting presents a natural, casual and organic artistic language. Its object image has an internal structure with a very strong constitution law, which is covered by the rich and natural changes of artistic elements however. Although geometry exists, it does not attach importance to the shaping of the volume sense of mountains, but creates a solid and stable sense of rhythm of two-dimensional pictures, which also results in the planarized and profound space of Chinese painting, providing an expression different from the traditional western landscape painting. This is actually the way Cubism wants to explore. In Chinese landscape painting, the Gestalt method is generally used to complete the viewer's psycho visual wander, thereby abandoning the volume and the sense of existence while shaping the image of mountains.

And this also creates another opportunity, because the purpose of shaping the physical image is no longer to produce a visual perception of the sense of light, dark and volume, however it still has to show the change of the image of the mountain body, therefore the focus of each side of the mountain body does not lies in its shadow relationship different from the other sides, but the change in space implied by the artistic elements. This kind of implication of image transmission can be conveyed to the cultivated audience by arousing the schema in their mind. Images can be extended in infinite space and time, and with the unique material carriers of Chinese landscape painting, such as long scroll painting, the

audience can experience a sensory journey of mountains and rivers as if traveling there in person.

5.Paraphrases in the Visual Image Design of the College of Art and Media, Tongji University

The logo design of the College of Art and Media is composed of seven graphics that gradually change from circular to triangular. Each graphic is like a spot of light with multiple colors superimposed to form a white border on the inside and a colored outline on the outside. Its combination form is flexible, and the seven graphics can be freely combined and transformed to form a logo with a sense of movement that represents the basic order and law in art (Figure 3-1). The image poster of the A & M College was constructed by using different superposition methods in the AI software. This poster is a metaphor for the internal spatial relationship of the College, the spatial journey of the College was transformed and refined in accordance with the research results of traditional landscape painting (Figure 3-2,3-3). Combining with theoretical research on traditional Chinese garden and the practical wayfinding system design in the next step, the VI system design of A&M college with wayfinding system design had been merged into one, which created a holistic and inclusive environment for the visiting teachers and students. While visiting the School of Media, they participated immersivity in the narrative of the college space, thereby a deeper impression of the college was created.

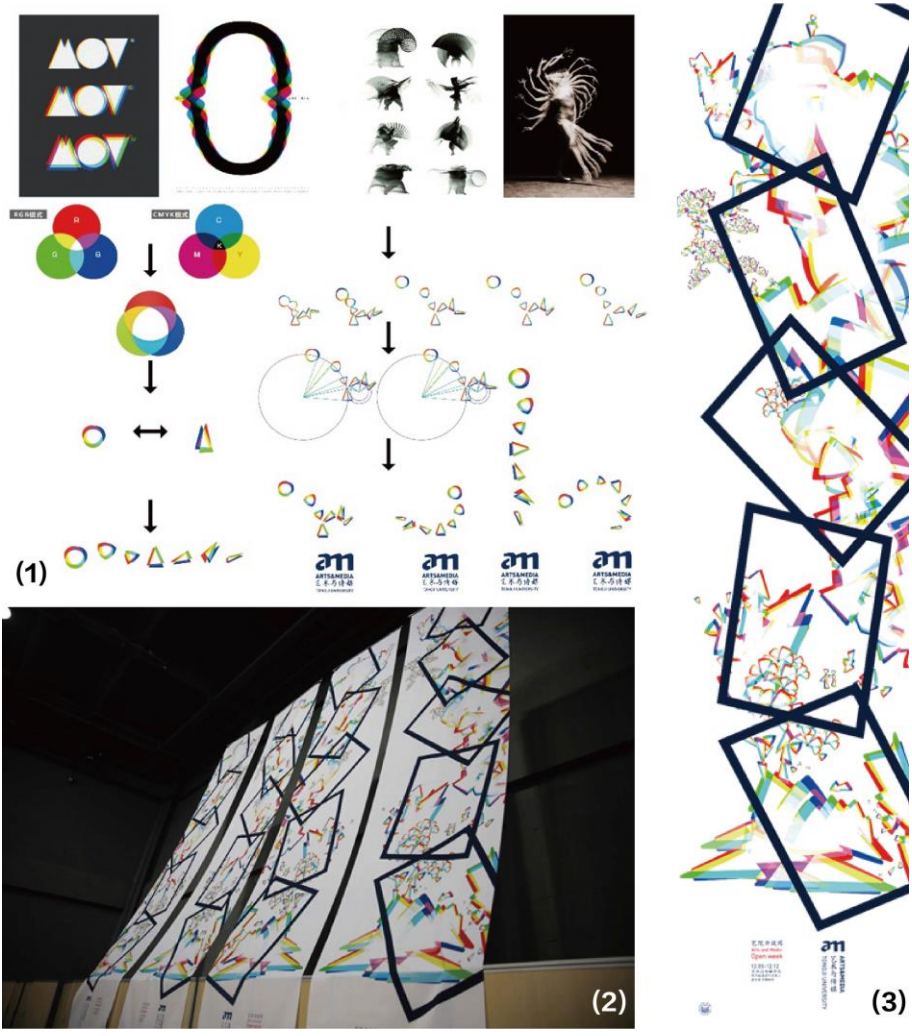

Figure 3. (1). The explanation of the Logo design process, design by Avril Accolla(2)/(3) The poster which represent the visual identity of A&M college according to the feature of space, design by Avril Accolla&Jixiang Jiang.

6. Conclusion

Human beings have tried to find the truths and mechanisms behind the cosmic space-time in the endless phenomena since ancient time, thus, different forms of carriers had been created to find and express the position of human beings. Visual perception, as the most

important sense, becomes one of the crucial parts of human creativity. However, vision is also the deepest sense that obscures us. China and the West have formed different visual and expressive systems during the past historical development independently, which continue to affect the development of their own cultures profoundly and subtly. However, in the past three years of research, what impressed me most is that human beings have more in common than what we show. The Chinese proverb says: tread different paths that lead to the same destination(Shu tu tong gui 殊途同归）, As human beings, our destiny is the same. Multicultural sustainable development and design innovation under its influence will be the source to reduce human ambiguity and to strengthen consensus. This has to be a work in progress which will never end and keep evolving.

The Interplay between Ethics and Aesthetics in Intelligent Systems-Users Interaction

Gabriele Barzilai[*a]

[a]Politecnico di Milano, Dipartimento di Design
*gabriele.barzilai@polimi.it

Abstract | In this paper, I address the interplay between ethics and aesthetics, in the context of everyday interaction with smart systems. This study is the result of a year's time development of my PhD research, whose general aim is to understand how people's beliefs and behaviours come to be shaped by the aesthetic experience with smart *things*. The expected outcome is a set of design strategies to integrate moral reasoning in the framework of design for behaviour change, relying on aesthetics *in* interaction. Preliminary results are presented, based on a literature review in the area of *aesthetics of interaction*. Although basic, these findings are helpful for they suggest that ethics and aesthetics in users-smart systems interaction are interdependent. This insight holds promise for the development of an aesthetics of moral reasoning, in the context of users-smart systems interaction. A research-through-design approach will be adopted in the remaining two years, with the aim of testing assumptions by means of working prototypes.

KEYWORDS | AESTHTICS OF INTERACTION, ETHICAL CHANGE, INTELLIGENT SYSTEMS, BEHAVIOUR CHANGE, RESEARCH-THROUGH-DESIGN

1. Introduction

As technology advances, the production of design mutates, and so does the experience of users (Lessiter, et al., 2014). In this respect, the advent of artificial intelligence and its widespread use in all sorts of application has led to a radical change in the way users interact with products, prompting researchers to focus on a new form of aesthetic experience (i.e., aesthetics of interaction) (Iannilli, 2015; Russo & Ferrara, 2017).

What makes this type of experience unprecedented is the responsiveness of the artefacts, namely, the dynamic change of the features of the artefacts in response to the user's actions. The result is a complex relationship developing between users and systems, where meanings, emotions and actions bundle in a dense network (Jacucci, et al., 2014).

In the body of this network, ethics comes to acquire a prominent role (Latour & Venn, 2002; Lukes, 2010). Indeed, moral values crystallise into artefacts and ethical judgement actively stands behind the user's decision-making process (Verbeek, 2008). The dynamic character of such a relationship between users and products engenders a form of aesthetics that gives the user's ethical reflection a practical dimension of application. When contextualised, thus, ethics proves tightly bound to aesthetics (Saito, 2007). An exemplar case in research is that of the Kantian and Romanticist vending machines (Ross, et al., 2009), where the aesthetics of the interaction was deliberately designed to elicit *good* behaviour in users according to specific ethical values. The Kantian vending machine, for instance, adopts a rationalist perspective, representing candies through a description of their constituent parts (proteins, sugar level, etc.). While interacting, users are reminded of their body mass index and finally asked whether they really want to proceed with the purchase. In this way, the type of aesthetics epitomises a deontic proposition, that is, a statement concerning what one should and should not do.

These studies show how ethics in smart system-user interaction takes shape, literally, influencing people's behaviour. However, in the large body of research on aesthetics of/in interaction, ethics and its connection with aesthetics is hardly ever addressed and never in depth. This despite the endeavours to broaden the notion of aesthetic experience by including the psychological dimension of the interaction between smart systems and users (e.g., (Hassenzahl, et al., 2012)). Strikingly, the same applies to areas most directly concerned with changing people's behaviour through design (see e.g., (Redström, 2006; Lilley, 2009; Tromp, et al., 2011)).

Overall, a crucial aspect of aesthetics of/in interaction remains under-explored: its power to change users' behaviour by embodying ethical issues. In particular, what misses is a specific aesthetic language designed for intelligent systems, which aims at fostering users' behaviour change by stirring moral reasoning. In the context of design for sustainability, this is a great lack as moral reasoning, when conscious, can strongly affect daily behaviour by pushing people to bring into question their own individual interests in the face of collective ones.

As part of a PhD research project, this paper proposes an expansion of the notion of change-through-interaction, which includes moral reasoning as an integral part of the decision-making process at the base of users' change in behaviour. The main result of a year's time development of the project is a preliminary understanding of the interplay between ethics and aesthetics in the users' everyday interaction with smart products. This knowledge is a starting point for the development of an aesthetics of moral reasoning able to foster the users' ability to change actively their beliefs and behaviours (see 4.1).

2. Literature review

2.1 Scope of the enquiry

The relationship between ethics and aesthetics in the interaction with intelligent systems is a complex matter, requiring a multidisciplinary approach to be understood. Thus, the areas of knowledge involved are multifarious, often outside the domain of design. In my research project, I am focusing on three main areas, which can be regarded as fundamental to gain a first understanding of the mechanisms underlying the relationship under investigation: *aesthetics of/in interaction*; *user's affective response*; *ethical awareness in interaction*. In this paper, I focus on *aesthetics of/in interaction*, providing a brief account of the main approaches and theories developed in this area.

2.2 Aesthetics of/in interaction

Aesthetic (as a quality of) experience

Since the notion of *user experience design* has gained popularity, the aesthetics of products and systems has come to be conceived as part of the relationship between users and things (Hassenzahl, 2010, p. 21). Aesthetics, in this view, is not a property of objects nor is limited to their appearance. Rather, it is a dimension of the quality of the user experience, i.e., the sense of beauty springing from the subjective appreciation of things through perception.

The long-standing idea that aesthetics resides within the things being judged comes from hundreds of years of aesthetic theory searching for universal principles that allow for generalisation (Krippendorf, 2005). In this perspective, the vocabularies and guiding principles that theorists have developed focus on artefacts, neglecting the role of the perceivers. This conception, however, has been challenged over recent years by several studies claiming that aesthetics cannot be treated separately from the individual who is judging. In this light, aesthetics is deemed as context dependent as well as culturally rooted (i.e., non-universal).

In today's design research, aesthetics is conceived as a quality of the user experience, directly related to the user's affective state (e.g., see (Desmet & Hekkert, 2007)). This

approach brings the attention back to people, namely, it focuses on the empirical phenomena pertaining to the appreciation of artefacts through senses.

Interaction: where the dynamic of aesthetics unfolds

The type of experience that users have when they interact with products has changed significantly over the last few years, due to the massive spread of artificial intelligence. Indeed, the dynamic change of the features of the artefacts in response to the actions of users gives rise to a new form of aesthetic experience. For this reason, researchers in the fields of HCI and interaction design have started taking an interest in the *relationship* (i.e., interaction) between users and intelligent things, there where the dynamic of the aesthetic experience unfolds. The understanding of aesthetics in HCI and related fields, however, is anything but shared. In this respect, Hassenzahl (2008) identifies three main approaches to the study of aesthetics: *normative*; *experiential*; *judgmental*. Such a distinction is part of a larger attempt to reduce the inconsistencies emerging from different studies on the subject. Despite this attempt, the recent studies on aesthetics of interaction often combine the three approaches. Moreover, researchers adopt different epistemological perspectives on human experience, making it difficult to reach a consensus. A brief account of the different views on aesthetics of interaction follows.

Phenomenological perspective

In their study on the aesthetics of "computational things", Redström and Hallnäss (2002) developed the concept of "expressiveness", focusing on the way things appear to users. The authors draw a fundamental distinction between the notions of *use* and that of *presence*. The latter refers to the "existential definition" of things, namely the way we accept things in our *lifeworld*, giving a place and a meaning to them. The researchers position aesthetics in the relationship between intelligent systems and users, applying a phenomenological perspective to its understanding. In this view, appearance acquires importance to the extent that it embodies the identity values that users project onto it as a consequence of an inner conceptualisation. Although the authors emphasise the "existential definition" of things – their *presence* in the inner life of users – aesthetics is viewed as part of an experiential dynamic, which involves both users and things.

Pragmatist perspective

A pragmatist viewpoint on aesthetics, based on Dewey's understanding of experience (Dewey, 1980), has been quite successful among researchers in the field of HCI and interaction design. In particular, Shusterman's concept of *pragmatist aesthetics* (Shusterman, 1992) has informed various strands of research on what is termed *aesthetics of interaction*. This approach affirms the central role of the socio-cultural context in the human aesthetic experience as well as its instrumental character in everyday life. Moreover, with the concept of *somaesthetics* (Shusterman, 1999), the body is considered an indispensable

part of the aesthetic experience. This view refuses the Cartesian separation between mind and body, claiming an ontological unity between the two. Although popular, this approach has been adopted (and adapted) differently by various groups of researchers.

Peterson, et al., (2004) developed a framework for the design of interactive systems, promoting the concept of aesthetics of use as an alternative to that of aesthetics of appearance. In this respect, they are in line with Djajadiningrat, et al.'s holistic conception of design for interaction (2002), which emphasises the role of bodily experience, user's motor-skills and action-related affordances. Following Shusterman, they strongly criticise the analytical conception of aesthetics, pointing out that merely promoting visual appearance proves to be a highly reductive and simplistic view on aesthetics, given the complexity of human experience – which includes feelings, emotions, actions, and movement.

Drawing on the work of Peterson, et al., Ross and Wensveen (2010) developed their own framework, with the aim of establishing a new design approach called "aesthetic interaction through aesthetic interaction". This approach builds upon the idea that the design of interaction with smart systems is too complex to be addressed by means of non-interactive media (see (Frens, 2006)). Such a shift from theory to practice is carried out through the design of a lamp, which is intended to generate a specific aesthetic interaction by eliciting human values such as social power and helpfulness. In this respect, the researchers pursue a method to integrate ethical values in the design of (smart) product experience, connecting ethics and aesthetics.

A different interpretation of Pragmatist aesthetics is offered by Lim, et al. (2007), who look at aesthetics of interaction through the lens of *interaction gestalt*, i.e., the abstract qualities of the interaction emerging from the user experience. From a theoretical point of view, interaction is seen as an abstract entity situated between the user experience and the attributes of the artefact. This conceptual separation, it is argued, allows designers to better examine the manifestation of the interaction gestalt, turning aside from a focus on the intrinsic properties of the artefact. In this respect, Lim, et al. are interested in the immediate level of the interactive experience, i.e., the "tight coupling between human sensory and materials", which is thought to drive experience itself. This moves away from the idea of experience as something unfolding over time within a given socio-cultural and environmental context. While embracing the concept of somaesthetics, Lim, et al. focus on the abstract and intangible aspects of aesthetic experience, leaving aside the physical dimension of interaction.

Building upon Shusterman and Petersen, et al., Löwgren (2009) offers a further theoretical contribution to the understanding of interaction aesthetics. Embracing a pragmatist perspective, he seeks an "inclusive" notion of aesthetics, which combines emotions, meaning and perception. Moreover, he highlights the distinction between aesthetic judgement and "factual reports on sensory impressions" (e.g., feeling cold or warm, seeing blue or green). Overall, Löwgren stresses the fact that the qualitative assessment of aesthetic experience does not necessarily reflect the degree of allure that such experience

elicits. As an example, horror films and similar experiences seem to be appealing to people even though they elicit negative feelings. Löwgren proposes four conceptual categories that describe the aesthetic qualities of interaction: *pliability*; *rhythm*; *dramaturgical structure*; *fluency*.

Critical perspective

Marching to a different drummer, Bardzell (2009) advocates the combination of two rather different philosophical traditions – *critical theory* and *theory of aesthetics* – to strengthen and advance designerly speculation in the field of HCI. The friction between the analytic and the continental philosophy reflects the tension currently alive between the scientific and the cultural dimensions of HCI. Indeed, design has a transformative vocation, which makes criticism and speculation two fundamental requirements. On the other hand, the need to understand the phenomena pertaining to user-system interaction requires the empirical approach of science. Hence, Bardzell views the merger of science and critical theory an opportunity for the field of HCI to advance in theory development. In this regard, he strongly criticises common-sense based definitions of aesthetics that proliferate in interaction design research, soliciting an aware and rigorous use of the concepts elaborated in this long-standing philosophical tradition. As a contribution to the field, Bardzell (p.2365) identifies and discusses four strategic roles that aesthetics and critical theory can play in HCI research:

1. *"Informing the existing design process";*
2. *"Resist[ing] or innovate[ing] on the design process*";
3. *"Develop[ing] theory"*;
4. *"Expos[ing] the consequences of design*".

3. Method

3.1 Epistemology

In my research project, I adopt what may be regarded as a *constructionist* perspective on how knowledge is produced (Darlaston-Jones, 2007). Indeed, I deem reality as *shaped* through socio-technical relationships, which are situated in specific cultural, historical, economic, and political contexts. In these contexts, individuals hold and develop their own interpretation of reality through the interaction with both the environment (natural and designed) and other individuals. In the realm of scientific enquiry, I believe that knowledge is a construction that researchers articulate into a rhetoric. This rhetoric uses a specific language and semantics, with the aim of claiming the trustworthiness of what is regarded as knowledge.

3.2 Approach to design research

As a methodology, I refer to *Constructive Design Research* (CDR) (Koskinen, et al., 2013), an approach similar to *Research through Design* (RtD) (Giaccardi & Stappers, 2017; Zimmerman, et al., 2007). Compared to RtD, this approach offers a wider interpretation of the term *design*, meant as a (research) practice where methods and theories borrowed from other disciplines can be combined and adapted in a constructive way, according to both the aim and the context of the enquiry.

In the preliminary phase of the project, I addressed my research question through a classical literature review. This phase was preparatory, however, to an empirical study based on a research-through-design approach. In this respect, my process started with "thinking analysing abstracting", to use a definition from the *Reflective Transformative Design* model (Hummels & Frens, 2011).

3.3 Methods of enquiry

In the first stage of my research process, I addressed the research question by reviewing relevant literature in the areas of *aesthetics of interaction*, *user's affective response*, and *ethical awareness in interaction*. In this paper, I give an account of the studies in the area of *aesthetics of interaction*, focusing on the understanding of the interplay between ethics and aesthetics in users-smart systems interaction. In this respect, my enquiry relied on a qualitative analysis of specialised academic literature on the subject.

In the remaining two years of my PhD project, I aim to conduct empirical research in the field, adopting a RtD-based approach (i.e., CDR, see 3.2). This entails the use of a diversity of methods for data collection and analysis, ranging from ethnographic to action research-based techniques. To specify, as far as the data collection is concerned, I expect to adopt the following methods: *cultural probes* (Gaver, et al., 1999); *prototyping* (Martin & Hanington, 2012, pp. 138-139); *diaries-questionnaires-interviews* (Goodman, et al., 2012, pp. 243-272). For data analysis, I expect to adopt the following methods: *grounded theory* (Muller & Kogan, 2010); *artefact analysis* (Martin & Hanington, 2012, pp. 14-15). As mentioned in 3.2, these methods will be adapted in the context of an RtD process.

The enquiry will be carried out mainly in the home environment, although the ubiquity of smart technology – which I address in my research – makes it difficult to confine the research to a specific context. As far as the recruitment of participants is concerned, I expect to adopt a *purposeful sampling* strategy (Rapley, 2014).

4. Results

4.1 Preliminary findings

The interplay between ethics and aesthetics in user-smart systems interaction

The findings here presented constitute a basic understanding of the complex relationship between ethics and aesthetics in the interaction with smart systems. Three research areas have been addressed: *aesthetics of interaction*; *user's affective response*; *ethical awareness in interaction.* The theory in the area of *aesthetics of interaction* informs much of my first understanding of the relationship under examination.

The following points summarise my basic understanding of this relationship.

1. *Relationship of interdependence*

All technological artefacts mediate our relationship with the environment, affecting our decision-making, interpretations, and actions. As mediators, they hold the ability to direct (i.e., to change) both our understanding and behaviours as users (Verbeek, 2008).

According to Verbeek (2008), morality crystallises into artefacts, following a twofold process: "pragmatic" (related to action) and "hermeneutic" (related to interpretation). Both forms of mediation happen in the context of human experience, which is characterized by cognitive, perceptual, and emotional processes through which people attribute meaning to their own possibilities of action and the related consequences. In these processes lies much of what is termed aesthetic experience. Indeed, aesthetics consists of a qualitative (cognitive) appreciation of the features of artefacts through senses (perception and emotions). Therefore, aesthetic experience is an essential part of the mediation to which technological artefacts give rise, i.e., it contributes to the meaning-making process originated in this mediation.

As put by Saito (2007), when moral judgements are based on the "sensuous features of the objects" they can be linked to aesthetics and regarded as "moral-aesthetic judgements" (p. 210). In this view, any judgements concerning the moral character of designed objects qualify also as *aesthetic* in so far as they are based on "first-hand experience" (p.211). Moreover, there are cases in which aesthetic judgements are dictated by moral beliefs in the first place (p.215). This is the case of normative values of social and cultural type, which influence (i.e., regulate) the criteria for the appreciation of beauty. Although Saito focuses on architectural design, this interplay between ethics and aesthetics can be extended reasonably to all designed artefacts.

In all cases, the socio-cultural context – moral values included – plays a crucial role in determining the type of aesthetic experience that users have when interacting with designed artefacts. At the same time, the aesthetic experience drives moral decisions by characterising phenomenologically the mediation between people and artefacts.

In brief, ethics and aesthetics seem to be *interdependent*, in the context of the interaction between users and designed artefacts. Indulging in a simplification, aesthetics contributes to shaping moral values, as well as moral values influence the aesthetic experience. Certainly, the way this happens is anything but linear, nor it can be reduced to a simple principle of causality. Rather, the complexity of this interdependence entails multiple forms, i.e., different roles played by ethics and aesthetics in their interplay, depending on contextual factors (both at the macro and micro levels).

2. *Higher space for communication*

Intelligent artefacts give rise to a peculiar type of user experience, given their ability to respond dynamically to the users' input. Besides performing complex tasks, sensors and smart materials allow for multi-layered, highly articulate forms of communication between users and systems. Such communication can even happen at a purely sensory level (i.e., non-linguistic) without diminishing its elaborateness. The peculiarity of this type of artefacts amplifies the range of possibilities in terms of depth of communication and intensity of the experience, which makes the previously mentioned *interdependence* between ethics and aesthetics of a different kind. Indeed, the type of aesthetic experience that users have with these artefacts is phenomenologically different from – possibly richer than – that generated by ordinary artefacts (i.e., non-interactive). Likewise, the moral reasoning that such a type of aesthetic experience elicits is conceivably more elaborate, allowing for complex propositions to be articulated. In other words, the greater space for communication (whether sensory- or linguistic-based) offered by intelligent artefacts paves the way for a type of relationship between ethics and aesthetics that is multivariate and can be deeper than in the case of non-interactive artefacts.

In brief, when users interact with intelligent artefacts, the interdependence between ethics and aesthetics can have many forms and be highly elaborate, given the higher space for communication that such artefacts provide compared to non-interactive artefacts. The enhancement, in this respect, is both quantitative and qualitative. This twofold enrichment does have implications for the kind of ethical issues that can be raised through (or embedded into) the aesthetics of the interaction with intelligent artefacts. To specify, the logical chain of links that some elaborate moral issues require in terms of reasoning could be addressed by means of dedicated intelligent artefacts, whereby the space of communication is high enough to permit such a conceptual leap.

4.2 Expected results

Short-term

The main result expected in the short run is an advancement in my basic understanding of the interplay between ethics and aesthetics in users-smart systems interaction. By completing the literature review – i.e., addressing the other two areas of research previously mentioned, *user's affective response* and *ethical awareness in interaction* – I expect to gain

an essential knowledge regarding the relationship under consideration. This knowledge, I anticipate, will allow me to plan a series of experiments to be carried out in the next two years (see *Long-term*).

Essentially, by accomplishing a thorough literature review in the two remaining research areas, I expect to be able to understand what forms the interdependence between ethics and aesthetics can take. After having identified interdependence as a significant attribute of the relationship between the two, I need to examine both the mechanisms behind moral reasoning and how the affective response of users influences their aesthetic experience.

Long-term

The results I expect to attain in the long run consist of theoretical constructs (e.g., frameworks) that can be used by other researchers in the future to advance in the enquiry pertaining to the relationship between aesthetics of interaction and ethics, in the context of design for behaviour change. It is worth to clarify that the results I aim to achieve are both of propositional (i.e., pragmatic or instrumental) and investigative (i.e., hermeneutic or interpretative) type. There is no contradiction between the two as empirical research in design does have such a dual spirit, as it were.

To achieve these results, I will conduct a series of field experiments, investigating the interplay between ethics and aesthetics in the users' everyday interaction with smart products (see 3.3).

5. Discussion

5.1 Towards an aesthetics of moral reasoning

The preliminary findings of my research suggest that ethics and aesthetics in users-smart systems interaction are interdependent. This paves the way for a deeper enquiry into the *forms* that such an interdependence can take and, more importantly, into the impact that these forms have on people's beliefs and behaviours, in the context of everyday practices. Indeed, the general aim of my research is that of integrating moral reasoning – and its interplay with aesthetics – in the framework of design for behaviour change. The reason is that ethics informs (in combination with aesthetics) the decision-making process at the base of users' change in both beliefs and behaviour. As a long-term horizon for my own PhD research project, I see the development of an aesthetics of moral reasoning, in the domain of design for users-smart systems interaction.

6. Conclusions

In this paper, I presented the preliminary results achieved in my first year of doctoral research. In my project, I am addressing the problem of how aesthetics in the interaction between smart systems and users embodies ethical constructs. In particular, I aim to understand how the interplay between ethics and aesthetics (of interaction) contributes to eliciting a type of moral reasoning in users such as to influence their beliefs and behaviours in everyday life.

The results illustrated are incipient, mainly based on a critical review of relevant studies conducted in the area of *aesthetics of interaction*. Although preliminary, these findings shed light on the relationship between ethics and aesthetics in the interaction with smart systems, suggesting that they are interdependent. The various forms that such an interdependence can take determine depth and breadth of the impact on people's beliefs and behaviours, in the context of everyday practices.

At this stage of the research, the findings seem to indicate that moral reasoning can be integrated in the framework of design for behaviour change by working on the way ethical constructs are embodied in aesthetics (i.e., aesthetics *in* interaction). A deeper investigation is needed to understand how to design for an aesthetics of moral reasoning.

The pluralistic aesthetics of nowadays design

Francesca La Rocca[a]

[a]Università della Campania "Luigi Vanvitelli", Italy
francesca.larocca@unicampania.it

Abstract | The paper aims to investigate some emerging phenomena of nowadays design culture, in order to find interpretative keys suitable to highlights new aesthetic dimensions of the project. The contribution results as a part of a reconnaissance in the field of international design, with reference to projects of the last fifteen years. Since the 1970s, a general crisis of Modernity, involves at the same time the founding paradigms of science and art. In this context the culture of design is nimbly able to take new paths beyond the International Style: designers responded constructively, realizing new generations of objects. The contribution proposes some cues for an interpretation of the post-industrial scenario, in order to suggest a set of key-words, emblematic of emerging aesthetics which liven up the latest design; aesthetics that result multiform and sometimes very distant from each other.

KEYWORDS | CONTEMPORARY DESIGN, MODERN SCIENCE CRISIS, NEW ART PARADIGMS, POST-INDUSTRIAL AESTHETICS

1. Paradigms of art and design at the turn point

The universal dissemination of neutral, grey, cold products has, with the International Style, was an expression of the desire to make an encoded quality accessible to everyone. The vaster attempt at conciliating industry and culture, made with great civil and spiritual strength by the School of Ulm, waivers when faced with the protest that in 1968 involves all society and the project too, and that coincides with the year the school closed. Rationalism, as a method tending towards homologation in the name of the scientific foundation of the project, excluded – at least in theory – a true aesthetic pluralism, in the name of a tendency towards formal purity.

The "dream of a world of goods ordered in a rational manner" as Stanislaus von Moos called it, fails to take hold in the new-born post-industrial society that hybrids different cultures, languages, styles and is therefore interested in new qualities of objects. In post-industrial age aesthetic paradigms fatally multiply; design hybridizes with art, confronts the new languages of the metropolis, the imaginary of goods, the new scientific imaginary linked to the advent of electronics, telematics and digital. The escalation of the environmental crisis also drives design towards eco-sustainable design and also towards Neo-organicism; the design culture necessarily interfaces in many ways with nature, also as an aesthetic phenomenon.

Two main conditions influence the transition from the modern to the post-industrial design, concerning deep changes in the paradigms of technology and art:

- the crisis of modern technical-science and the ecological matter undermine the roots of the project and result directly in the questioning a vision of the object as merely optimization;
- the modernist concept of art comes into discussion, with its idea of the existence of a mainly representative current for each period in history; instead the acceptance of a multitude of methods and conceptions takes hold. (Danto, 2008).

Although affected by this double crisis, that regards its deeper matrix, the culture of design comes out of it strengthened. In the post-industrial era design uses its ambiguity amongst the worlds of art and technology as an opportunity; it finds inspiration and new energies in all areas of science, as well as facing up open-mindedly to the world of art.

Danto claims that the end of Modernity coincides with the impossibility of art finding a single direction. Starting from the 1970s, the succession of art phenomena over time would no longer be interpreted as the obsolescence of one style through a subsequent form of art, considered able to fully represent the present era. "It is now a widespread believe that the atmosphere of the last quarter of a century, characterised by incredible productivity and experimentation in the visual arts but lacking a single narrative approach that can exclude competitor ones, has become the norm". (Danto, 2008, p. 13)

What Danto observed in the field of art is clearly reflected in what is happening almost simultaneously in the field of design culture. Starting from the 1970s, design increasingly takes on more pluralistic aesthetic.

Strange families of objects claim their presence for the first time so strongly, with the exhibition "Italy: The New domestic Landscape", in 1972 at the MoMa of New York. It's the realistic response to the crisis of a monologic aesthetics, a different sensitivity – in this case pervaded by ironic vein of Pop Art.

Starting as Avant-Gardes, Archizoom and Superstudio, UFO group, Ettore Sottsass jr, Ugo La Pietra, 9999, Heinz Frank, Coop Himmelb(l)au, Max Peintner, Haus-Rucker-Co, Raymund Abraham, are just some of those who contributed to launch a new front of projects, at first mainly provocatively; but they suggest a real, proper alternative to the black and white of International Style, unleashing a wave of aesthetic freedom that has never been exhausted to date. The objects exhausted their role as mirrors of an abstract Rationalism: people begin again to recognise itself in the warm imperfection and in the variable characters of the new artificial world.

2. Notes on the metamorphosis of object in post-industrial age

In the 20th century art gives us, as Werner Haftmann claims, the prehistory of our contemporary relationship with things. He identifies a series of approaches on the last century's painting scene that constitutes the object of values and references (Haftmann, 1972, p. 12-13)

- The power of the archaic object, the sensitivity for the magical-creatural, animistic element, the value of fetish (from Rousseau to Picasso);
- The solemnity and essential dignity of the common, forgotten things, little objects (e.g. De Chirico, Savinio, Morandi);
- The mythology of the machine or most banal device or technical object. (e.g. Léger, Duchamp);
- The mythology of lightness, fastness; the aesthetic of the energy and fluxes in technological world (Balla, Boccioni)
- The poetic potential of the refusal, the advance, the unpleasant (e.g. Schwitters, Moholy-Nagy);
- The object of dreamlike value (e.g. Dalì, Ernst, Magritte).

In post-industrial age designers take a fresh look at that part of Modernity, full of unresolved problem areas, visionary, full of creative energy, which could be fully expressed in the painting and figurative arts of the 20th century. At the same time, they demonstrate the capacity to act as a sounding board for social and personal needs and desires, to crossing new urban languages, to interact with the world of goods and that of fashion. Product design, services design, urban design, materials design, web design, interaction design,

experience design, bio design, dressing design, textile design... since the 1970s to nowadays, the discipline has progressively opened to the most varied languages, technological worlds, interdisciplinary contaminations. Crossing into so various cultural and artistic contexts post-industrial design generates objects which sometimes have an indecipherable character – and for this reason attractive – certainly difficult to catalogue according to the old aesthetic parameters.

In this context so rich, but also apparently chaotic two main guide-concepts influenced the metamorphosis of the object in the post-industrial age: the *biological* and the *immaterial*; an age defined by Michel Serres as "soft" because it can overcome the harshness of the industrial age. The two fundamental sciences of poster-modernity are identified by Serres, not by chance, with the sciences of living and telematics (Serres, 2016, p. 238).

The *biological* responds to the more general accusation brought against the traditional object: things are deaf and immobile, whilst living things are versatile, sensitive and changing. The *immaterial* regards the possibility of overcoming the solid nature of the object, in favour of a more ethereal, interactive object. The biological therefore looks to the transformation of the inorganic into the organic, to the metabolism of the object as a crucial point of view; the immaterial investigated the new artificial objects allowed by digital and electronic technology, that has redeemed the traditional things from its relational inertia. (La Rocca, 2017, pp. 68-70).

The biological and the immaterial have also acted as guide concepts by which to overcome that aridity of the object caused by its rapid emptying of symbolic, religious and magical values that took place with Rationalism (La Rocca, 2017, p. 83).

Based on this critical reconnaissance, our research has explored the international scenario of the nowadays design project, which reveals some influential categories, identified by some keyword. They help us to interpret the contemporary project as deviation from its most rigid modern matrix and, specifically in this case, to highlights new aesthetic trends. The article selects emblematic examples, by designers who are particularly active on the international scene in last years.

The nowadays design aesthetics includes not only various, but sometimes contrasting, declinations, even false affinities between phenomena of very different meaning. In the next paragraph we will analyse emerging aesthetic issues, linked to: the relationship with nature, to which the designer approaches by acquiring skills in biotechnology or, simply, for a symbolic and figurative inspiration; the two opposite poles of a deliberately modest object or a fetish-object, charged with symbolic energies and overflowing to excess; the relationship with materials and their free invention, within a direct laboratory practice by designers; a tendency towards dematerialization that stops at an impassable frontier: the inescapability of our body. So that aesthetics takes on its most literal value, as an exaltation of the five senses for a cognitive access to reality and its beauty.

3. Divergent aesthetics of the nature: living objects and bare nature

The *living object* of contemporary design can transcend two limits of the traditional object of Modernism, which is limited to being mechanical, rigid, unable to transform and evolve. The living is not an object generically inspired by nature, nor necessarily associated with eco-sustainability, but it tends to be concretely made of living elements; this implies a strong identity and aesthetic imprint.

As Blaise Cendras wrote, “life is efficiently, manifestly, formally space and time sublimed, merged, aromatised. It is honey”. Indeed the living in contemporary design is a key word that irresistibly draws in designers and without doubt the strongest declination of the *biological*.

In recent years, specific design researches move along the increasingly flexible boundary between the object and the living system. The attraction for the biological, of the avant-garde utopian aspiration (i.e. Metabolism, William Katawolos, Rudolph Doernach) today can take advantage of the continuous and fast new acquisitions of scientific research and biotechnology. Design conjugates in new forms chemical research, bioengineering, advanced materials, creating interesting short-circuits between science, technology and art.

New designer figures interact with interdisciplinary teams and several exhibitions investigated in last years these new frontiers. Among these, *Design and The Elastic Mind*, the exhibition organised by the New York MoMA in 2008; *Biodesign. Nature, Science, Creativity*, again at the MoMA in 2012; *Synthetic: Art and Synthetic Biology*, at the Natural History Museum of Vienna in 2011; *Grow your Own*, presented in 2014 at the Dublin Science Gallery.

Design takes on the governance of experiments, the purpose of which may be each time mainly artistic or technical. A great variety of researchs and projects emerges today, involving organisms on all scales, from plants to bacteria, algae, fungi or individual cells. Eric Klarenbeek e Maartje Dros with the project *3D Bakery,* Sonja Bäumel with *Bacteria Textile*, Naja Ryde Ankarfeldt with *Microbial Skin*, Suzanne Lee with *Biocouture*, Aniela Hoitink with *Mycotex mycelium textile dress* work in this direction; they are all representative of an expansive design research that includes textiles for fashion, sustainable packaging, attempts at mutating dynamic graphics, as in the project *Symbiosis* by Lan van Abbema. A special design award "Bio art and design", was assigned in 2016 to the designer Angelique Spaninks for the project *Fluid Matter.* The Officina Corpuscoli’s researches, develops a new paradigm for the project: the slogan “growing design” identify the possibility of a diffuse industrial product, processed by the action of living organisms.

Figure 1. Officina Corpuscoli, in collaboration with Sonja Bäumel, Co-de-iT, WASP e Waag Bio-logic. Living structures and swarm bodies, *2013 ongoing. Interactions between biological and digital computing, in the forms of Slime Mold and 3D printed architectures.*

Among the aesthetic trends regarding the relationship design/nature, we can identify another key-word: *bare nature*. In this case the deterministic vision strictly connecting functionality/aesthetic, which Rationalism saw in the systems of nature, is completely out of play. The substance of the project is the natural element or event, such as the growth of a plant, the chemical reaction of a mineral, grass and earth, a common stone, all in their symbolic value.

We can rather refer this new kind of aesthetics of nature to the anti-deterministic vision that Roger Caillos observes in many phenomena: “Man is free, clumsy, sometimes perverse”. In the natural world, organic or inorganic, beauty is sometimes completely enigmatic and inexplicable. “Without knowing anything, thanks to an impenetrable metamorphosis, the lepidopteran draws gaudy wings from the indistinct mixture that fills the nymph. Man puts the risk of a deliberated, doubtful decision between himself and his work” (Caillois, 1998, p. 36)

Germano Celant comments on the movement of *Arte Povera*, which in the late 1960s conquered an important role on the international art scene. “The artist-alchemist organises living and plant things into magical facts, working to discover the real heart of things, to find them and exalt them. His work does not, however, look to use the simplest materials and

natural elements (copper, zinc, earth, water, rivers, lead, snow, fire, grass, air, stone, electricity, uranium, sky, weight, gravity, heat, growth, etc.) for a description or representation of nature; what interests him is instead the discovery, the presentation, the insurrection of the magical, wondrous value of the natural elements" (Celant, 1969, p. 54).

We can adapt these words to the defining, many years later, research, projects and exhibitions that underlie new critical visions of nature. Some significant examples of a bare nature design include Sayaka Yamamoto's researches, as *Little Wonders*; Zanellato's work, *Affinità naturali*; the research by Tomás Gabzdil; Francesco Faccin, with his *Allevamento Domestico*; Ferreol Babin, with the project *Fusion Containers Drawing*. The exhibition *Post Fossil Excavating 21st Century*, by Lidewij Edelkoort – featured for the first time in 2011 at the Design Museum Holon in Israel –, mixes freely fake palaeontological findings, the matter of the fossil, and the theme of primitivism.

Designers today show a great interest for the natural element as a fragment that can be drawn from without mediation, or for a manipulation of the material with the alchemy-type laboratory style. Dissonant interpretations of a relationship with nature, however rich in symbolism and made of hidden references to the mystery that is intrinsic to it.

Figure 2. Giorgia Zanellato, Affinità naturali, *2014.*

4. Object with a mini-ego and fetish object

An object with a mini-ego expresses a design quality that has apparently withdrawn into a minor sphere, but many designers make their small gestures and discrete intervention into a form of poetry and aesthetics. A mini-ego object mainly refuses the arrogance of costly products, the object as a status symbol to flaunt.

As Maurizio Vitta observes, “the philosophical thought has contemplated the world of everyday experience with suspicion, keeping it at a respectful distance at all times. Being unable to deny it entirely, it has merely ignored it, at most very hastily noting its distant presence”. (Vitta, 2012, p. 182). But the world of everyday existence, of the object as minute being, in any case re-emerges

Already at the end of the 1970s, Félix Guattari was talking about a transformation of society based on a microscopic scale, a real *molecular revolution* (Guattari, 1977). Social utopia and revolutionary hope have made way for everyday micro-utopia, given that any overly direct critical position of society appeared to be in vain. In approaching the preparation of a design philosophy, Bruno Latour identifies an escape route from a *muscular artificiality* in the care and attention to detail, for a world of objects that instead contemplates material, morality and sustainability. (Latour, 2008)

In the book *Sale fino, Nuovi sapori del design italiano*, a design generation attentive to a minimalist object, apparently as modest as it is refined, is presented by Beppe Finessi. There are projects by Lorenzo Damiani, Paolo Ulian, Joe Velluto; but also Aroundesign, that with the simple cutlery *Moscardino* wins the XIX edition "Compasso d'Oro" Award. (Joe Velluto, 2005)

A panorama of the mini ego objects has significantly represented also in several exhibitions: *ReDesign The Daily Products of the 21st Century*, by Kenya Hara in 2000, commemorates the 100th anniversary of the Japanese company Takeo Co; *The New Italian Design*, presented by Silvana Annicchiarico and Andrea Branzi at the Triennale di Milano in 2007, that showed many projects in this line; *Microfacts* by Stefano Maffei in 2016 at the Milan Subalterno, a series of micro objecst by 14 Italian designers.

What is certain is that the objects are studied very closely indeed, not to force them into a sort of obsessive ergonomics or in the myth of the technical precision, but rather for a new attention to microsociology of the everyday, its imagination and gesture.

Figure 3. Modoloco Design, La dignità del tassello*, Microfacts 2016. Each wall plug is conceived according to a particular style, from modern to contemporary design.*

Apparently opposed to the minimal object, we find another key-word, *the fetish*. It represents a reaction to the "soul-less" object of the Rationalism, to the long exclusion of the iconic-irrational, the anthropomorphic and the zoomorphic form the project.

Gillo Dorfles was one of the first, in the 1970s, to reintroduce the subject matter of the affective relationship with objects, connecting this to the expressive intensity and mythopoeic load of the pre-industrial object. In this context, he returns to the idea of the object-fetish as a reaction to the idea of the closure of the industrial product in the pure values of rationalism and as a new tendency towards the ritual and the symbolic. (Dorfles, 1988)

From his vast anthropological research, Claude Lévi-Strauss appears to also draw the following general consideration: fetishism is not a fogging of the "wild thought", but rather it has an *excess of meaning* of which man can make the most to know the world. (Lévi-Strauss, 2010) Is it unthinkable for western, civilised man to imagine a quid of life in the inanimate object? As Marc Augé points out, "what is perhaps more unthinkable is pure material, mineral homogeneity: it has to be animated if we are to understand it and start to consider it ". (Augé, 2002, pp. 23-24) Animism, therefore, apparently diametrically opposite the inertia of the raw material, at a more careful reflection appears to complement it.

For Karl Marx, fetishism is "a device that can subvert the relations between the animate an inanimate, between the material and the imaginary and project onto things a close-knit set of expectations, symbols and affective values." (Fusillo, 2012, p. 22)

The fetish object is in fact first and foremost one that opposes pure efficiency, refuses to disappear into its mere function alone; it thus charges itself with a mysterious power, becoming enigmatic and impenetrable in its violation of the boundary between people and things. (Carmagnola & Ferraresi, 1999)
Today's fusion of the fetish with electronics, smart materials and advanced technologies introduces a particularly interesting declination: the sense of the archaic blends with the concrete possibility of making it an animated device.

The most emblematic exhibitions related to the theme is *Fetishism. Obsessions in Fashion & Design* (Trapholt Museum, Denmark March 2015 - January 2016) organised by L. Edelkoort, P. Fimmano and W. Schenk. It exhibits objects of approximately 100 designers, including, Maarten Baas, Marcel Wanders, Jaime Hayon, Iris van Herpen, Walter van Beirendonck, Studio Job, Kiki van Eijk, Bokja, Bertjan Pot, Christien Meindertsma, Claudy Jongstra, Iris van Herpen, Rick Owens, Undercover and Phoebe Philo. The settings are divided up into ten themes, including nudism, sadomasochism, absurdism, consumism, romanticism, legendism, shamanism and spiritualism, all relating to a sort of fanaticism and obsession for the object and its details.

Figure 4. Fetishism, the exhibition by Lidewij Edelkoort, in his first version at Milan Fuorisalone, 2014.

The aesthetics of the fetish and the mini-ego object, although they seem to be opposites, can they coincide? Probably in the irony of Modoloco design, where small hardware

elements, wall plugs, each one takes on an iconic value. The obsession with detail is, on the other hand, as characteristic of fetishism as it is of design.

5. Sensory and neo-material aesthetics

The *sensory* key-word identifies a reaction of design culture to the devaluation of the empirical knowledge, implicit in modernist methodology, and the exclusion of the varied sensory range from the centrality of a project, all focused on vision. The traditional object is, by its very definition, an isolated entity, unable to interact, destined only to be observed.

From the point of view of Modernism, the object lies in a space marked out by geometry, which is interpreted as a direct filiation of the renaissance: as in the Renaissance, form is reduced to abstract schemes and a system of syntactical relations, the eye therefore plays a neutral role of observation. (Payne, 2011, pp.76-77) The object is simple, glossy, made up of elementary forms and lives in a space that is basically sexless, with no noise or odour, illuminated as day with no penumbra; the fundamental qualities of an environment or object can be ascribed to the coherence of form, structure and functional needs, rather than to be experience-based.

Clino Trini Castelli and Branzi in the 1970s develop the *Design Primario* movement, focusing on the *soft qualities* of the products and the environment. They collaborated with various Italian companies on the development of products endowed with new aesthetic values: chiaroscuro, the environmental music, the microclimate, the olfactive and tactile aspects and material finishes; all the aspects of perception neglected by Rationalism become material for the project (Castelli & Petrillo, 1982). The expansion of the discipline of design beyond the hyper-defined object and towards the concept of experience today moves along this line.

The Ying Gao's interactive clothes of the project *Incertitudes*, the work *Olfattorio* of Cristina Celestino, the project *Nascosto* by Officina Corpuscoli, based on an amplified sound by bacteria, the project *Anthropomorphic Sensory* by Lesley Ann Daly, are some emblematic examples of a design propensity to valorise a large sensory range. In the work of Usman Haque, the presence of the human body can interact with devices for a single sense, as in his projects *Sonic Environment* or *Scents of spaces*. MachineHistories group with the project *Cymatics Display,* feels the need to transform pure data from the Internet into tangible matter and sensory relationship.

The user is immersed in an iridescent concatenation of flows and stimuli that tend to involve it emotionally. The aesthetics, we can say, reaches his most large meaning – once present in the vibrant, multi-sensorial interior of gothic cathedrals –, neglected by Renaissance and thus by Rationalism.

Figure 5. Bruce Munro, Tili Wiru Tjuta Nyakutjaku *, Uluru, Australia, 2017.*

Figure 6. MachineHistories, Cymatics Display, 2014. A device that generates waveforms through water, managing in real time data from an Audi's social campaign.

The key-word *neo material* is linked to the sensory but concerns the production process rather than the user's experience. The neo-material appears in fact as a reaction to the scission of thought, machine and hand, characterizing the standard production of the modern industry.

Today designers appear to refuse the hidden, separated production process and declare, in multiple manners, the value of a free invention of their material world. Producers in the first person, devoting their time in certain cases to the development of specific machinery. “The neo material comes within the folds of the most advanced experiments, moving between scrupulous laboratory research and an investigation into the machines and materials used for the direct construction of the project” (Scarpitti, 2017, p.131).

A scenario that is at the opposite end of a model in which industry is delivered the abstract matrix, the project, that the machine will automatically be set to develop and replicate. In the staff laboratory, in the individual process, instead, *something* always happens.

We can mention the research conducted by Studio Formafantasma, on natural polymers, by Lucie Libotte, on dust, or Aliki Van Der Krujs, on rain, by Jolan van der Wiel, through a blend of magnetic powders and pigments. In the project B/NDALTAAU Revital Cohen & Tuur van Balen, invents a new mineral recovered by old hard disks.

Figure 7. Studio Laura Daza, DIY Colour Recipe Book, *2014.*

"Heterogeneous, unexpected, organic and inorganic materials, digital instruments and machinery; everything is positioned in a single synaesthetic space that is the laboratory. This intersection of vision and techniques gives rise to the most unforeseeable products" (Scarpitti, 2017, p. 132). The strength that the final project releases can prove to be proportional to the energy released into the production process, the direct working of the material, with all its imperfection and rejects. The virtual and the dematerialisation perhaps reach their bank and unsurpassable limit not only in the mineral hardness – that in any case characterises the world – but in the essential corporeity of man and his hands.

6. Design at a forefront

As shown, design continues today to play a forefront role, using ever-new ways to become an interpreter of the metamorphosis of the object: softened or cruel, material as a stone or immaterial as a sensation, indifferent, minimal or excessive, ...anything but annihilated.

The multiform aesthetics in design we note today, can be interpreted as specific answers to the critiques that have progressively invested the cold object of International Style. The *biologic* and the *immaterial* however represent the underlying matrix of contemporary design sensitivity; two concepts apparently distant, but concordant for an evolutionary, light, performative artificial world. A world complex because interwoven with values and qualities: the closeness to nature and the valorization of the human experience of making, in multiform senses and perspectives. The most advanced design looks after both.

Will be so plural also the future aesthetics of design? We imagine yes, unless the future has a *new glance* in store for us, capable of flattening art, reality and technology under a new light, stronger or with the same intensity as Rationalism.

The role of vernacular typography in the linguistic landscape of multicultural Singapore: A multimodal analysis case study of a gentrified street

Min-Yee Angeline Yam

Nanyang Technological University
angeline_yam@ntu.edu.sg

Abstract | The art of typography has been receiving a fair amount of attention at the crossroads of linguistic landscape, garnering the interest of sociolinguistics. Technological advancement has pushed typography to the forefront alongside traditional modes of communication. It is therefore no longer viable to limit the analysis of communication modes to just speech and writing but to also consider typography as an important semiotic mode for meaning potential in its own right. This paper attempts to present a case study of analysing the vernacular typography of a gentrified street (Haji Lane) in Singapore through a multimodal analysis approach. The results provided preliminary insights into how Singaporeans through the creative expression of typography and language use, assert their 21st-century multicultural identity alongside the nation's de facto language – English, in a situated gentrified urban environment. The study also contributes to an on-going endeavour of semiotizing typography as a mode for rational explanation.

KEYWORDS | LINGUISTIC LANDSCAPE, TYPOGRAPHY,

MULTIMODALITY, SEMIOTICS, VERNACULAR TYPOGRAPHY

1. The relationship between linguistic landscape and typography

Linguistic landscape is an emerging field that refers to the "display of visible written language"(Gorter 2013, p.190) in a public domain taking into the social-cultural context that it's situated in. Linguistic landscape is hugely underpinned by prominent linguists Scollon & Scollon's (2003)'s concept of its geosemiotics framework, arguing that the study and interpretation of signs and language should take into consideration of its placement in the material world. The multi considerations of linguistic landscape thus require a cross-disciplinary analysis (Gorter, 2013). According to Gorter(2013), linguistic landscape is an "ecological arena"(p.197) that considers not only the modality of written text but also considers other modalities such as oral, images, objects, and placements situated in time, space, and people associated with. It can also be used as a research tool to understand language trends in urban spaces and the way in which users use the languages are also especially helpful to understand issues of multilingualism (Gorter, 2012).

Machin (2007) and Leeuwen (2006) called for the consideration of typography as semiotics in its own right so as to expand the linguistic analysis of traditional communication modes beyond that of just writing and speech. Designers Baines & Haslam (2005) also highlighted the disconnection of typographic studies and the features of language calling for more joint investigations of the two highly interconnected fields – language and typography. Machin(2007) argued that linguists have often neglected works from visual and media academics but at the same time, there is also an obvious lack of linguistic engagement within the field of visual communication.

The multi-dimensional nature of linguistic landscape thus opens up opportunities for scholars to rethink the traditional modes of communication which have been primarily speech and writing and call for consideration of other aspects of communication that language and signs are situated alongside in. The art of typography in particular has recently been receiving a fair amount of attention at the dynamic crossroad of linguistic landscapes around the world.

Creative designers, Banham (2011), Villagomez (2015), and Woodward(n.d) started documenting series of letterforms found in the urban environment and posited how cultural and historical changes affect typography evolution of the city. In Hong Kong, there is emerging anthropology and topology research of bi-lingual typography of the city's vernacular neon signs creation and other everyday signage (Lou, 2016; Chen et al, 2014). In London, designer Hyndman(2016) has been conducting typographic tours since 2013 in the Dalston area of London with the aim of paying homage towards the working-class history, also embarks on a series of typographic experiments on how the visual display of typefaces has the power to affect our everyday decision making. Curtin's(2015) research into the playful linguistic landscape of Taipei's commercial signage took into considerations not only the verbal and written communication but also the visual treatment of commercial signage

interpreted. In Singapore, academics have been looking into various shopfront signages in recent years particularly from a multilingual perspective (Shang & Guo, 2017; Hult & Kelly-Holmes, 2019).

2. Situating typography in linguistic landscapes

Typography is often seen as secondary to the meaning of the written content as it's often associated as a technical craft of aesthetical legibility instead of an important semiotic mode in its own right (Baines & Haslam, 2005; Leeuwen, 2006; Serafini & Clausen, 2016). However, the ease of technological advancement means communication work in public spaces that are used to be done only with the use of language now shares the responsibility with the art of typography making. (Baines & Haslam, 2005; Leeuwen, 2006).

The importance of the relationship between typography and linguistic landscape is further revealed by Banham's (2011) documentation of typographical signs seen around a city arguing that sign reveals cultural stories that have the potential to converge different disciplines together, allowing the audience to relate to typography to a "larger cultural experience"(p.14) and creating new avenues of heritage appreciation. Baines & Haslam (2005) likens typography to inventions of the wheel and electricity that "underpins modern Western Life" (p.10). Lupton(2010) and Hydnman (2016) demonstrates how the creative usage of typeface choices and treatments are not only of legibility or aesthetical consideration but provide contextual narratives that the typefaces are situated in. These examples highlighted by creative designers align with Scollon & Scollon's (2003) geosemiotics framework of signs and language analysis putting typography in the limelight of linguistic landscapes.

The definition of typography has hence evolved over the years from simply the study of its legibility (Warde & Lange, 1980) to the creative arrangement of text and typefaces efficiently as a visual system of processing information and word-based knowledge transmission (Ambrose & Aono-Billson, 2011; Baines & Haslam, 2005; Hoeks & Lentjes, 2015;). In recent years, the definition of typography has started moving away from the aesthetical ability and functional means to a much more conceptual definition described by Ambrose & Harris (2017) as "the means by which a written idea is given a visual form" (p.6) rendering typography's capacity to influence communication in our everyday contemporary society.

Technological advancement has made it easier for anyone to arrange text and images in different combinations (Machin, 2007). Not only do designers have greater access to software tools to express communicative functions through the art of typography, but the untrained layman can also attempt to create typography for communication with greater ease than before. Thus, it has become a comfortable subject of discussion in everyday conversation and is acknowledged as an important expressive element of our everyday culture (Banham, 2011). The ease and rise of typographic presence in our everyday urban

spaces including the retail environment testify to the importance of the role that typography plays in communication and thus in the linguistic landscape.

3. Typography as a semiotic resource for analysis

Typography – a subject area within the domain of graphic design as the art of typeface arrangements has emerged to be an important mode of analysis with meaning potential (Curtin, 2015; Hult & Kelly-Holmes, 2019; Lou, 2016; Serafini & Clausen, 2016; Shang & Guo, 2017; Järlehed & Jaworski, 2015).

This is largely due to the on-going attempts of systematically organizing the subject as a semiotic system by academics of various fields which includes linguists, semiotician, and designers (Ambrose & Harris, 2017; Baines & Haslam, 2005; Hyndman, 2016; Leeuwen, 2006; Lupton, 2010; Machin, 2007).

In order to consider typography for analysis at the crossroads of linguistic landscapes, it is important to establish typography as a semiotic mode in its own right with its own set of grammar and lexicon. Linguist Van Leeuwen (2006) noted the potential of typography as a medium with its own lexicon but noted that it lacks "complex grammar" (p.154) to consider it as a mode. Without an established set of grammar – analysis thus becomes unsystematic.

Van Leeuwen(2006) then made a pioneering attempt to argue for typography as a "means of communication in its own right" having the capacity for fulfilling Halliday's (1978) three broad communication functions of ideational, interpersonal, and textual. Analyzing distinctive features of typography such as type weight, type manipulation, type connectivity just to name a few for the meaning potential that each features produces. Van Leeuwen (2006) attempts to present a systematic way of semiotizing typography not only with its lexicon but at the same time figuring out whether it may have a set of complex grammar.

The graphic design domain whilst less established than it's linguistic counterparts had since seen various endeavours by visual design academics in recent years to conceptualize typography as a systematic resource, breaking down visual cues into basic components to develop a typographic lexicon and grammar that can serve as rational choices and explanation within a context instead of depending on abstract intuition.

Visual design academics are now presented with opportunities to reference it's established linguistic counterparts to examine typographical visual written form playing out in linguistic landscapes with its own set of typographical lexicon and grammar.

Ambrose & Harris(2017) deconstructed typography in all manners of it's visual cues from the style of typefaces to the way it's being used, at the same time providing various visual examples located in the material world of how the visual cues provided meaning potential in the context of communicating messages across. Hyndman (2016) highlighted typography in the manner of how choices of typefaces can potentially influence decision making processes

in our everyday environment. Lupton (2010) provided explanations of how layout alignment variations could communicate different moods and messages. All of these point to an on-going endeavour of demystifying typography as simply an abstract art of visual text arrangement.

4. The multimodal analysis

The concept of multimodality in linguistic advocates for the analysis of communication of both visual as well as textual. Advocates of the multimodal concept encourage academics to move away from traditional monomodal analysis, i.e analysing only just text or just visuals, and instead take on a holistic approach of semiotics analysis to move forward with the way communication advanced beyond just text and content (Kress & Leeuwen, 1996; Machin, 2007). The framework for a robust multimodality analysis is however still controversial and lacking (Leeuwen, 2006).

5. Purpose/research question

This paper hence attempts to present a small-scale case study of analyzing the vernacular typography of a gentrified street (Haji Lane) in Singapore via a multimodal analysis of both the text and it's visual form, and through the process, allows it to reveal potential cultural, social and historical narratives of Singapore's multicultural linguistic landscape.

Through this small-scale case study, the paper aims to respond to the above backdrop by contributing to the search for a more robust analysis framework of communication work done through typography.

6. Shop signage analysis through the lens of vernacular typography in Haji Lane

Vernacular typography in this paper refers to the art of creative textual arrangements created by ordinary people, who may or may not have any typographic training. Vernacular typography is usually differentiated from globally recognized standards of typography making and reading. Created by the everyday ordinary people, vernacular typography reflects the everyday voice of the environment it is situated in rendering it a suitable choice of analysis for linguistic landscapes. Amongst the variety of vernacular typography, signage has been considered as an important "visual fabric of a neighbourhood" (Banham, 2011) and shop signage is especially vernacular due to it's "bottoms-up" nature of creation (Shang & Guo, 2017) and has provided rich materials for analysis in various linguistic landscapes research (Lou, 2016). This paper hence proposes to analyse four shop signage in Haji Lane located in Singapore.

7. Methodology

7.1 Research site

Haji Lane has been chosen as the street for analysis due to it's recent years of gentrification from historically a quiet Muslim residential quarter to a trendy lifestyle hotspot for young Singaporeans and tourists alike. Independent shops set up by young designers and entrepreneurs offer an array of lifestyle options from fashionable wear made locally to eclectic vintage wear, of food and beverages that pride its' local origins and inspiration (Walk Down Haji Lane in Singapore, 2017). Haji Lane has in recent years became the epitome of an ideology determined to move away from the standardization and homogenization of offering due to the effects of globalization, providing Singaporeans and tourists alike an alternative form of consumerism.

7.2 Data collection

Four shops that operate on Haji Lane have been chosen as the sample for analysis. The four shops are chosen on the basis that each shop offers a different nature of business from each other to reflect the diversity of offering on Haji Lane. The shops were also chosen on the basis that the main language used on the shop front signage each reflects the diversity of the four main languages of Singapore - English, Chinese, Malay, and Tamil. However, no Tamil was found to be used as the main language of the shop front signage on Haji Lane. Thus, Tamil representation is missing from the sample size.

The criteria of analysis are such that each shop will be analysed for its shop front sign and one other supporting visual collateral. In the study of branding, the visual identity of a business goes beyond that of its name on the signage but is interlinked by a series of other elements to communicate the brand offering (Slade-Brooking, 2016). Hence the author attempts to also analyse a second visual collateral that supports the business communication for a more holistic representation of the typographical communication that it's situated in. As per the shop front sign, the second visual collateral must deem to be displayed explicitly in the public eye.

Table 1: Comparison of the types of supporting visual collateral in addition to the shop front signage across four shops in Haji Lane, Singapore

Name of shop	**Good Luck Beerhouse**	**The Singapura Club**	**家 Jia**	**Mokita Cuisine**
Types of business	Beerhouse	Contemporary Indian and Malay cuisine	Contemporary female fashion retail	Traditional Malay cuisine
Main signage	Shopfront sign	Shopfront sign	Shopfront sign	Shopfront sign

Supporting collateral	Secondary sign	Secondary sign	Stairways	Banner

Machin(2007) and Leeuwen(2006) both of whom are linguists attempted an inventory of typographical features which typography can be semiotized to create a 'typographic profile'. This paper however proposes to consider three other features as part of the inventory in an attempt to decipher the meaning potential behind the typographic treatment of each shop and by extension provide a more holistic overview of the linguistic landscape of Haji Lane. This paper will hence analyse the following three suggested modes employed to highlight any meaning potential:

1. **language choice** of the shops' signage
2. **typeface classification** used in the typography creation and
3. **type hierarchy methods** employed

Due to word restrictions, the author will present only two examples of analysis in each of the above categorization.

8. Analysis and findings

8.1 Language choice

Singapore is a multicultural society with four main languages (English, Mandarin, Malay, and Tamil) being used and spoken with English as the official communication. It is important to consider how these languages are being visually displayed and juxtaposition with each other reflecting the cross-cultural spirit of the street.

From table 2 below, English is seen to be present in almost all the shop front signage and in all of it's supporting collaterals. All shops have an additional language used apart from English, either as part of the shop front signage or on it's supporting collaterals. This reflects a very diverse representation of the business and the way each business wants to project its identity for the customers. The usage of Tamil language is however missing from the sample as no shop features Tamil as the main language of any shop front signage.

Table 2: Comparison of the language used on signage across four shops in Haji Lane, Singapore

Name of shop	**Good Luck Beerhouse**	**The Singapura Club**	**家Jia**	**Mokita Cuisine**
LANGUAGE FEATURED				

Shopfront signage	English	Romanized Sanskrit, English	Chinese,PinYin (official romanized Chinese)	Malay, English, Arabic
Supporting collateral	English, Chinese	Romanized Sanskrit, English	English, Chinese	Malay, English, Arabic

***Image 1**. Signage of 家Jia – contemporary female fashion retail. Left: Shopfront signage. Right: Stairways (supporting collateral)*

家Jia *(contemporary female fashion retail, see image 1*) - shopfront signage did not feature any English words but instead a romanised version of the Chinese word 家 which means *'home'* and has been translated into English pronounced as *'Jia'. 'Jia'* does not mean anything in the English language but for an audience who is bilingual in both English and Chinese, *'Jia'* becomes an accompanying English name to the Chinese name of the shop. The supporting collateral is a mixture of English and Chinese language. English is used to describe the type of fashion wear that the shop retails while the shop's name in the Chinese character 家 is repeated on the stairways. This perhaps suggests that while Chinese is used for the shop front but when it comes to the description of its products, English became the choice of communication.

Image 2. *Signage of Mokita Cuisine – a traditional Malay cuisine restaurant. Left: Shopfront signage. Right: Banner (supporting collateral)*

Mokita Cuisine *(Traditional Malay cuisine, see image 2)* - the shop front signage features Malay, English, and Arabic language. *'Mokita'* does not mean anything in the Malay language but when deconstructed, *'kita'* means *'us'* and is a recognized Malay word. Adding the word *'Mo'* to the front of *'kita'* suggests it's probably a Malay shop vendor's name. The word *'Cuisine'* is in English. By combining a Malay name with an English noun, it suggests some form of Malay authenticity to the dishes served while communicating to potential customers who are likely to be English speaking. At the top of the signage is the use of Arabic depicting an Islamic phrase of morning prayers. The supporting collateral is a combination of the same three different languages as used for the shop front signage - English, Malay, and Arabic. English is mostly used to describe the kind of dishes served in combination with some Malay words such as *'Satay'(meat skewers*) or *'Ayam' (chicken).* At both top corners of the supporting collateral is the well-known Arabic phrase pronounced as 'halal' which refers to a form of animal slaughtering adhering to Islamic law according to the Koran. This is in turn translated into its English pronunciation below.

8.2 Typeface classification

Typeface classification is often categorized according to their historical origins and by extension, its inherent characteristics (Ambrose & Harris, 2017; Lupton, 2010). This means each category typically possess some similarity of characteristics and reflects a certain narrative associated with a particular era or culture.

Table 3 below shows a variety of typeface classifications used that is beyond that of the Latin system categorization reflecting diverse creativity of representation of the business. However, as per the language used, the use of Latin type classification is still prominent in all

of the shop front signage as well as the supporting visual collateral due to the prominence of the English language.

Table 3: Comparison of typeface classification used across four shops in Haji Lane, Singapore

Name of shop	Good Luck Beerhouse	The Singapura Club	家Jia	Mokita Cuisine
TYPEFACE CLASSIFICATION USED				
Shopfront signage	Slab Serif	Modern	Archaic Chinese script, Neogrotesque	Latin script, Arabic script
Supporting collateral	Latin script, Chinese brushstroke characters	Modern, Grotesque	Calligraphic script, hand lettering, Transitional	Humanist Sans, Arabic script

Image 3: *Signage of Good Luck Beerhouse – a beerhouse. Top: Shopfront signage. Bottom right: Secondary sign (supporting collateral)*

Good Luck Beerhouse *(Beerhouse, see image 3)* – the shop front signage uses a very heavyweight slab serif typeface with British historical origins reflecting a British–styled pub appeal but yet the accompanying visual collateral features bold use of Chinese characters in brushstroke style demonstrating the desire to assert the business's Chinese identity at the same time. It is perhaps suggestive of the Singaporean's bilingual pride and patriotism while offering locally brewed beer.

Mokita Cuisine *(Traditional Malay cuisine, see image 2)* - uses the Latin script to visualize the shop's name in English but at the same time also uses the Arabic script on top of the shop's name illustrating Muslim's morning prayers of good wishes. In the supporting collateral, a banner, Humanist Sans typeface which is a very legible san serif typeface is used to describe the type of food served in the restaurant accompanied by the Halal sign in Arabic script again. Both the shop front signage, as well as the supporting collateral, uses the Latin system of alphabets as the main communication and both are accompanied by Arabic script indicating the Halal food it serves, distinguishing itself as a dietary choice catering to the Muslim community.

8.3 Type hierarchy methods

Type hierarchy is the concept of expressing the importance of communication via the arrangement of the visual written word. It can be done through a variety of typographical methods from scale to colour and can also be done via placement or orientation. (Ambrose & Aono-Billson, 2011)

Table 4 below shows a variety of methods identified used to create salience. The use of scaling (i.e. larger type sizes) appears to be prominent followed by stylizing of the typefaces and use of contrasting colour. The placement of type appears only in ***家****Jia's* shopfront signage perhaps due to the top-down method of reading the Chinese language. Despite the variety of methods employed, creating a larger type size seems to be a prominent method of communicating it's various business narrative.

Table 4: Comparison of type hierarchy methods employed across four shops in Haji Lane, Singapore

Name of shop	**Good Luck Beerhouse**	**The Singapura Club**	**家Jia**	**Mokita Cuisine**
TYPE HIERARCHY METHODS EMPLOYED				
Shopfront signage	Uppercasing, contrasting colour usage	Stylized typeface, larger type size, uppercasing	Stylized typeface, large type size, placement	Stylized typeface, large type size
Supporting collateral	Large type size, contrasting colour usage	Large type size, contrasting colour usage	Larger type size, heavy type weight	Uppercasing, contrasting colour usage

Image 4. *Signage of The Singapura Club – Contemporary Indian and Malay cuisine restaurant. Right: Shopfront signage. Left: Second sign (supporting collateral)*

The Singapura Club *(Contemporary Indian and Malay cuisine, see image 4)* **–** the shop front signage has the word *'Singapura'* highlighted via a larger type size and also via a stylized version of the Modern typeface used. 'Singapura' is an Indianized Malay word and an old name for Singapore (Government of Singapore). The word is no longer used to describe Singapore but frequently heard of in the country's national anthem that is sung and written in the de jure Malay language. By highlighting this word as the first hierarchy of the signage highlights a desire to reminiscent Singapore's nostalgic past and displaying patriotism at the same time. The supporting collateral highlighted two words *'Singapura Club"* through type size and colour in equal measures suggesting the effort to emphasize a modern twist with the *'club'* word added to the nostalgia *'Singapura'* name communicating a brand that is in creative dichotomy.

家Jia's *(contemporary female fashion retail, see image 1)* - shopfront signage highlighted the Chinese character as the top hierarchy through type size and a top-down type placement reflecting the desire to demonstrate an association of Chinese culture by reading from top to bottom, however, it's supporting collateral type emphasis turned to the emphasis of English words such as *'Accessories'*, *'skirt' or 'Footwear'* describing the type of fashion wear that the business retails. This potentially suggests that the Chinese character is used as a front façade for the shop but when it comes to the description of its products, English became the salient choice of communication.

9. Conclusion

Language is intrinsically linked to typeface classification. While the use of the English language and hence the use of the Latin type classification is prominent, this research showed clues of businesses demonstrating various cultural, social, and religious offerings though the use of other languages and typographical systems beyond that of English and the Latin system. This suggests a creative entrepreneurial method of distinguishing themselves from the homogenization of lifestyle offering that is usually found in regular shopping malls where most signs and languages are likely to be restricted by mall landlords to reflect the nation's de facto English language. The lack of language restriction use in Haji Lane means small independent businesses can assert cultural, social, and religious offerings through various "designerly" typographical modes. The study provides preliminary insight into how Singapore's bilingualism education policy of using English as the main language of communication while mother tongues acted as cultural connections have translated into an innovative vernacular method linguistically and typographically to distinguish the Singaporean identity pragmatically – using the English language and Latin system of designing to communicate it's offering while employing various mother tongues system of designing to assert it's Asian identity. This small research sample is not entirely comprehensive of Haji Lane's linguistic landscape but it provides a sneak peek into the discourse of 21st-century Singaporean youth's search of their cultural heritage through the expression of typography amidst their consumerist lifestyle.

Abstract | This paper explores the soft, fluid space in between disciplines that allow for an expansion of creativity. Disciplines often employ their own diverse modalities to express their work, including verbal vocabulary. The paper is an extended case study into a cross-disciplinary project between fashion design and dance students at LASALLE College of the Arts, Singapore. The project uses origami as a shared provocation. While origami tends to be a set of instructions aimed at arriving at a specific form or figure, in this project, paper folding, more specifically the concept of the fold itself, was used in loose, abstract and organic manner to allow students to explore it as a language responding to visual, haptic and verbal stimuli.

Pedagogically, the project resonated with methodologies utilized within the Bauhaus curriculum. The Bauhaus educator and artist, Johannes Itten, worked with material tactile play, drawing exercises and sensorial activities that were 'mediated through the body' (Jeffrey Saletnik) as part of his pedagogic practice. As Itten has stated in Design and Form: The Basic Course at the Bauhaus and Later (1963, p.8) young people who "begin with market research and practical and technical work seldom feel encouraged to search for something really new". This paper looks into the ways this project, allows students 'strengthen' imagination and creativity. Utilising preparatory workshops observations, students' journals and final performance, the paper will detail the 'collisions' and resulting tensions of disciplinary languages that results from cross-disciplinary collaborations.

KEYWORDS | CROSS-DISCIPLINARY, SOMATIC, BAUHAUS PEDAGOGY, FASHION DESIGN, DANCE

1. Introduction

This paper explores the soft, fluid space in between disciplines that allow for an expansion of creativity and vocabulary. Creative disciplines often employ their own diverse modalities to express their work, including verbal vocabulary. In this project, students from the Diploma in Fashion and Diploma in Dance collaborated together utilising shared provocations that are not specific to their disciplines, specifically rooted in the concept of the 'fold'. This paper delineates the fourth iteration of the 'Origami as Movement' project, with a focus on open, organic and porous manifestation of the technique of origami – *ori* (folding) *gami* (paper). The project, by beginning with paper folding and Gilles Deleuze's (1993) description of the fold as a process that is not fixed or punctuated, developed into choreographies and garment design that are elastic, anti-form and habitable. The paper will reflect on the project through both fashion and dance disciplines, and upon the visual and kinaesthetic language that developed in the collaborations.

2. Context

The high stakes in the world's coveted schools means that the pursuit of fashion and design education often comes at a high financial and personal cost to students (Doyle, 2020), with little space for exploration, failure and risk-taking. This has given rise to designers that enter the industry ready with a palette of result-driven and tested formulas that cater to the market. As Itten has stated in Design and Form: The Basic Course at the Bauhaus and Later (1963, p.8) young people who "begin with market research and practical and technical work seldom feel encouraged to search for something really new". For innovation to happen, creativity has to be prioritised over the market-driven design processes.

The creative process at the Diploma in Fashion typically follows prescribed steps and approaches to provide students with a consistent working style to suit the industry. These are also common steps found in several guides on fashion education (Renfrew, 2009). Studying the brief, doing secondary and primary research through observations, target audience and market research, material research, explorations with existing technical patterns or draping on an industry-standard body form. The students then move into a prototyping (the toile) stage where the garment sample is made and altered for fit. It is after this stage where the final garment is made with the actual fabric or material.

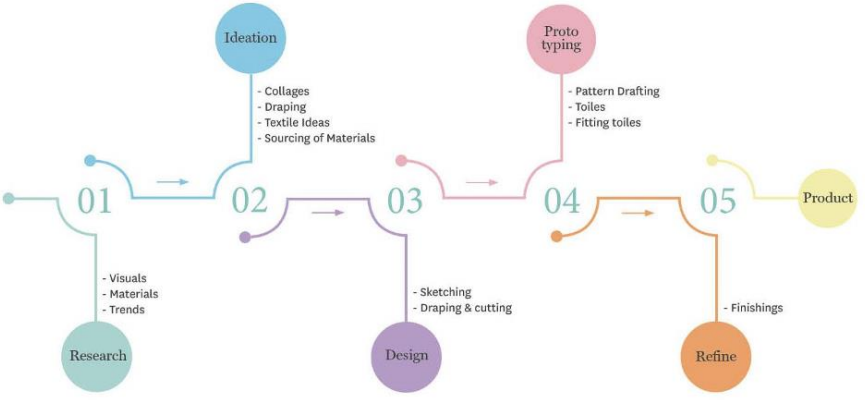

Figure 1. The roadmap in working on creative briefs at the diploma level at the Diploma in Fashion typically follows Figure 1. The process is usually linear and has limited bandwidth for circular revision.

It is important to note that the students at the Diploma level are mostly in their late teens to early twenties, with little to no experience in art and design before embarking on the programme. A large portion of the students enrol in the Diploma directly from public secondary schools. The primary and secondary public-school education system emphasises on testing as a form of meritocracy, this in turn discourages innovation, risk-taking and creativity. The project was initially conceived as a response by the Programme Leader to include a brief that was devoid of market constraints to increase risk-taking and experimentation.

At the Diploma in Fashion, students respond to targeted trends and audiences, all the while still mastering fundamental skills. In their third and final year of the Diploma, students have the necessary technical skills to approach more experimental and cross-disciplinary approaches to design. It is at the first semester of the final year that the said cross-disciplinary project takes place.

Similarly, the dance students enter into the Diploma course studies with a lack of experimental experience. Their early training tends to be focused on recipe driven forms and styles with little or no improvisational exploration to yield risk, play and agency within their choreographic making or ideas in and around the art field and performance.

The project had 3 aims:

1. To expand **creativity** through multiple modes of research, risk taking and play;
2. To encourage **fluidity** through cross-disciplinary collaboration;
3. To do the above through the experience of **somatic exploration**.

2.1 Expanding Creativity

As Paul Kleiman (2008) states in his research on creativity— the term evades strict definition and is often at odds with curriculum frameworks. There was a need to adapt the curriculum structure to accommodate a project that was not assessing the merits of the final garment as per industry. To privilege process over final aesthetic, the feedback and evaluation was centred on the aspects of the designed objects that allowed for an expansion in choreographed conversation with the dance students. Feedback and assessment for this project was thus adapted to also include a photo logging as reflection, using visual-heavy social media platform Instagram. Within this cross-collaborative project, intentional limitations set in the brief and the selection of workshops were meant to disrupt the students' usual design process.

Another way this project aimed to expand creativity was to remove market constraints. The global fashion system is firmly established root and branch in the ecosystem of fashion trends, market demands and supplies, seasons, manufacturing, supply chains and target markets. This creates challenges at the vocational level for a programme to introduce divergent forms of practices or approaches in conceptualising and developing a fashion collection. The brief intentionally disregarded these constraints and instead, the students were encouraged to collaborate with the dancers in a constant dialogue that allowed both garments and choreographies to respond to each other. The briefs, when stripped of market constraints gave rise to the exploration of new perspectives.

2.2 Fluidity

With regards to creativity, one should not be inclined to lock down a specific definition or approach. It can and should be viewed as an activity described and nested within a whole host of parameters such as: proactivity, intelligence, play, openness, courage, patience, listening, intuition, rigour, and wayfaring. Embracing these, an individual's creative practice can be elastic and ready to focus and respond to the specificity of limitations that arise in the moment. By yielding a learning place that is porous and fluid, the students are supported to go beyond their 'default mode' of working. Riding the currents to constantly question 'what if…'.

This particular project hones in on the students' process. Through each stage of the process varied obstacles arise; how can they be empowered to shift, yield, expand, distil— from their inherent modes of making? Beginning with a fluid landscape in the opening workshop, continuing through a dialogue of equally sharing body, garment/costume and movement as one shape-shifting being, this collaboration provides a buoyant platform to expand learning and creativity.

In fashion studies and academia, definitions have been important to add rigour to the study of fashion which has often been seen as a frivolous discipline. In the seminal book "Dress and Identity" Joanne B. Eicher and Mary-Ellen Roach-Higgins (1995) define *dress* as an

assemblage of body modifications and supplements. This takes dress away from the Western-centric fashion system, and can include non-Western aspects of permanent modifications such as tattoos or ephemeral modifications such as perfume. The term *garment* has connotations of manufactured clothing produced in assembly lines devoid of culture specificity. On the other hand, 'unwearable' or garments made for performance and not for everyday wear are referred to as *costume*. The definitions of garment-costume-dress shift and overlap throughout this extended case-study, at times even becoming a shell or vessel to the wearer.

2.3 Somatic Exploration

An increased interest in embodiment and somatic research methods in fashion point to a desire to better integrate the lived, physical body into fashion studies (Entwistle, 2000; Entwistle, 2015; Negrin, 2016; Ruggerone, 2017). Despite the intricate connection between body and garments, fashion is often studied and accepted as a primarily "visual, expressive, and aesthetic practice" (Robinson). Lewellyn Negrin, a feminist aesthetics scholar, points out that by shifting emphasis to the embodied, tactile and kinaesthetic experience of clothing, fashion studies focus on what the body *does* and not just how it appears.

By including the perspective of a somatic practitioner into the workshops and tutorials, the project attempts to integrate the language of movement into the vocabulary of the designers. Soma, coming from the Greek for body, "...any individual embodiment of a process, which endures and adapts through time… remains a soma as long as it lives." (Hanna, 1976, pp.30-34). Somatic movement educator and therapist Martha Eddy writes "In somatic studies, the body is perceived as the source of human intelligence - one learns through the living body." (Eddy, 2016, pp.7-8). Somatic practices, desire a quest for "tuning in", thus they incorporate methods such as touch, exploring with eyes closed, honing in on individual senses, covering mirrors and utilising language filled with rich imagery landscapes. All these activities hone in on the body, on how movement feels and its qualities, not how it looks. The focus is not on form; however, forms do arise, but from an internal stimuli. By creating a 'somatic learning environment' the somatic data not only informs, but also transforms (Batson, 2014, p.128). The instructions (or better yet invitations) are directed toward discovery, rather than goal attainment (Batson, 2014, p.131). By initiating the project through somatic tasks around the chosen theme and encouraging this knowledge to be iterated throughout the process, all students are supported within an exploratory, somatically informed environment.

3. Extended Case Study Results

This extended case study is informed by qualitative research methods including workshop and tutorial observations throughout the seven weeks of the term (October-November 2019), discussions between tutors from the Diploma in Fashion and Diploma in Dance, analysis of the final presentation/performance and individual student reflections. A total of 15 groups made up of 56 fashion design students and 15 dance students, each group worked to develop a choreographed piece. The cross-collaborative project was punctuated with a variety of intentional interventions and provocations as well as specific meeting points where lecturers from both disciplines would be timetabled for shared consultations with the students. The authors, lecturers from the School of Fashion and the School of Dance and Theatre will articulate the challenges and success of this project from their individual perspectives, including the 'collisions' and resulting tensions of disciplinary languages in cross-disciplinary collaborations. Most of the fashion design students were graded very highly in this project due to the shared workload and the focus on process, play and the allowance the garments/costumes gave the dancers in their choreography.

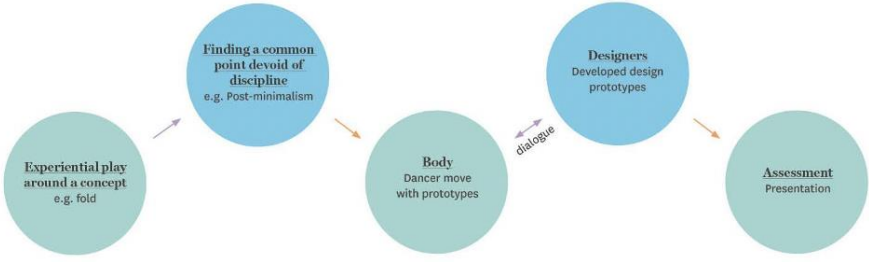

Figure 2. The roadmap for this project was unlike the student's usual linear design process seen in Figure 1. From Body to Designers, there is a constant dialogue and revision process.

Honing in on somatic practices which are process orientated and focused on embodied learning, the students were encouraged to enter into the concept of 'folding' through tools or activities including explorations involving movement, touch and the visual. While origami tends to be a set of instructions aimed at arriving to a specific form or figure, in this specific iteration, paper folding was used in a more organic manner that allowed students to use it as a language responding to visual, haptic and verbal stimuli. Furthermore, the project adopted the visual arts, specifically that of minimalism-post-minimalism-anti-form, as the thematic baseline from which each practitioner responded to. Students were explicitly discouraged from going into their individual disciplines for visual research, thus yielding a more expansive palette in their responses which can be seen in some of their reflective journals. In Figure 2, the exploratory journey is illustrated not as a linear process, but at times a to-and-fro

dialogue that supported an expansion of creativity as well as greater specificity in editing for both garments and choreographic gestures.

3.1 Preparatory Workshops

At the start of the project, the idea of the fold was introduced. To paraphrase Deleuze; the smallest unit of matter is not the point but the fold (1993). Seeing the fold and folding having infinite dimensions and possibilities. Experiential tasks stimulated a novel way of understanding the fold and engaging with the activity of folding. Working from breath and internal visualization, noticing tasks, sight and haptic drawings as well as play with paper, tissue and fabric allowed for a nonverbal 'ways in' of understanding and play.

As the workshop continued layers of other information were added helping to shape and yield specificity to their dialogue and collaborative engagement. Of particular note on Table 1, the final activity for the workshops included timed responses to images of art works projected on the screen; these timed activities were introduced to encourage intuition-based responses. First, through verbal responses, then spatial where students made 'prototypes' out of paper directly on the Dance student's body. Fashion students were encouraged to record these experiments and utilize them as design prompts for their own studio work.

Table 1. Breakdown of shared somatic workshop for designers and dancers.

Activity	Intention
Starting point from a theoretical place, *the fold.* Layering with biological, visual art, architectural sources.	Giving a basic understanding to the fold regardless of discipline.
Engaging in different experiential modalities to find ways in: meditative somatic exploration of fold/folding through breath and imagery, searching for folds within the site via sight, drawing a fold from sight, drawing the same fold from touch, exploration of folding onto paper in a more playful, roaming manner. Lastly, students invited to curate space with their folded paper sculptures and clothing they brought in of varied forms, textures and qualities. Dance students entered into this landscape improvising via language prompts into a deeper folding improvisation witnessed and archived by the fashion students.	Diverse somatic activities, encouraging play regardless of discipline.
Challenging them further with another limitation, rooted in the visual arts, the movements of minimalism, postminimalism and anti-form.	Encouraging shared vocabularies regardless of discipline, by utilising artworks from minimalism, post-minimalism and anti-form.
Introducing the technique of origami (paper folding) but not to achieve a certain form (e.g. cranes) rather drawing out its underlying principles of *hill* and *valley.*	Reducing the technical aspects of *origami* to the fold, regardless of discipline.

Using 3 specific artworks from Minimalism-Post-Minimalism-Anti-form as prompts, inviting the students into a collaborative immediate response.	Stimulating 'play' within a structured format.
First into words of activities/qualities to the examples (for 3 minutes), then transferring these ideas directly into paper (5 minutes) to the dancer's body.	

It was in this final activity that the material play, noticing and drawing of folds and even the verbal vocabulary to describe form, was synthesised. In Figure 3 one group's word association as a response to the art works projected on the screen can be seen. The vocabulary is associated with form—lines, shapes, textures and rhythms. They have no direct relation to garment silhouettes, fabrics or even colour. In Figure 4, we see the same group's timed response to Eva Hesse's artwork *Area* (1968), the words they associated with it were "constant-wavy-repetitive-layered-crawling-crumpled-uniform". In Figure 4, we see the dancer has taken an active bodily state/form inspired by the same artwork ("crawling") and the Fashion students began pleating and laying the paper on parts of his body ("layered", "repetitive"). Their body language is engaged with the dancer's 'crawling' body. Their response is highlighted as many of the groups worked in a static manner mimicking the way one would work with the dress mannequin as seen in Figure 5, with even the physical body language of the students creating a gulf between designer and 'mannequin'.

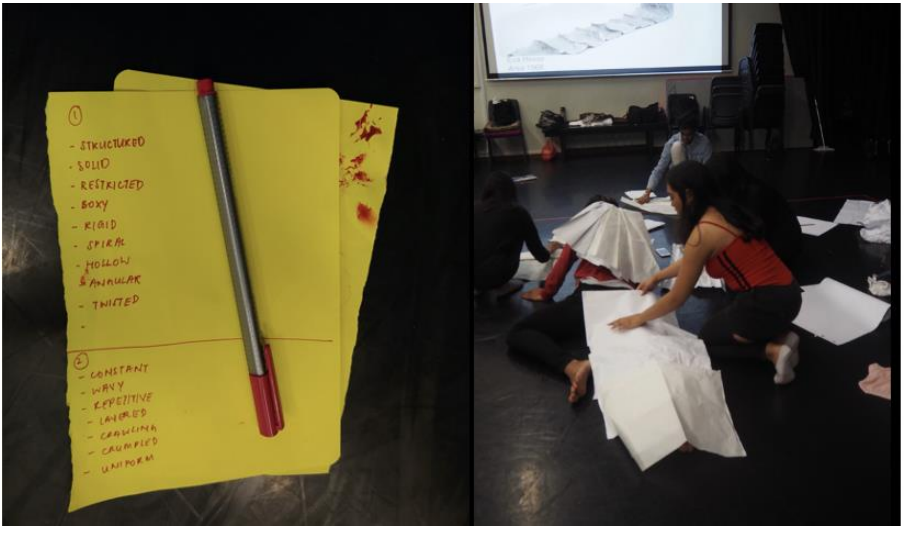

Figure 3-4. Group A's response. The second set of words on the yellow paper were key words the students associated with Eva Hesse's Area 1968. In Figure 4 (right), the students translated it into a spatial response, with the dancer adopting 'crawling' as a pose, which was one of the keywords in Figure 3.

Figure 5. Group B's response was more static, with the fashion students treating the dancer as a mannequin or dress form, instead of a moving body.

3.2 Development: Moving Away from Default Modes and Working through Conflict

After a day of workshops, the students then began working in their separate disciplines with the ideas they had generated as a starting point. The fashion students met weekly for the next five weeks during their design studio consultations where they had three supporting Fashion lecturers and a Dance lecturer. The personal process of development was archived through photo logging (Instagram), which encouraged immediate reflection with a medium that most of them use daily. The following examples are highlighted to show how the *to and fro* between dancer and designer opened a new languaging as well as possibilities of making, be that garment and/or movement. The creative focus was on risk-taking, fluidity, wayfaring and novel solutions. This was shown through projects that moved away from the habitual, migrating through conflict and expansion of their understanding of garment.

Once the fashion students were back in their studios, they tended to go back to their default modes. Shaatees from Group A, which had responded dynamically during the combined workshops, began using conventional methods to communicate such as sketching on a female fashion *croquis*- an elongated body used in fashion illustration, even though their dancer was male, as seen in Figure 6. The first prototype they made was more like a wrapping around the body (Figure 7-8), and they were told to consider it expanding to a larger scale to allow the body more space and affordance. There was resistance from the student to try ideas directly on the body, without first sketching them out, as can be seen in conversations between the student and lecturer. It took a very intentional and continuous

reminder to consider the dancer's possibilities of movement and to stay away from discipline-centred research.

Figure 6. Group A student's Instagram photo log shows the student going back to default mode in his communication of garments. Even though his group's dancer was male, he illustrated on a female croquis. An elongated fashion figurine used in fashion drawings.

Technical skill can be a constraint, but also allows different possibilities. Group A's idea was reduced further and their technical abilities developed a garment that was light, flexible and in the choreography, was treated like a 'shell' that the dancer was able to slip on, off and around within his choreographic work.

Figure 7- 8. Group A returns to conventional ways of designing to the body, with the folded fabric covering the dancer's body and creating a decorative surface with limited possibility for interaction with the garment.

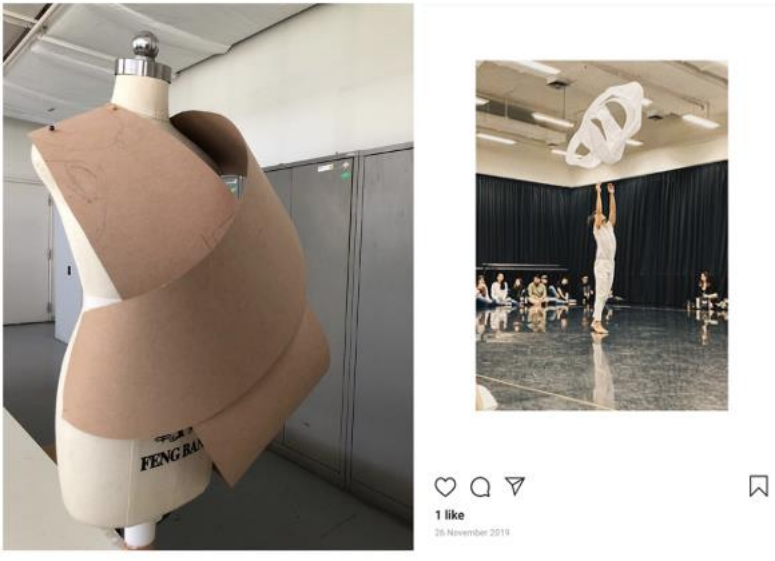

Figure 9-10. Group A is forced to return to form, and not decoration, they prototype a simpler idea as seen in Figure 9. In Figure 10, student's reflective journal shows their wonder at how their garment becomes an object in flight.

Figure 11. The final performance of Group A's garment shows the garment becoming shell and inhabited by the dancer's body.

For Group C, the beginning of the process was rife with conflict; with group members wanting to take different directions—from decorative to minimal. In the reflections of Daswani and Kim, we can see repeated descriptions about the mathematical calculations and technical know-how the project needed. In Figure 12 taken from Kim's photo log, we can see that the group prototyped different ideas, beginning with visual references to Richard Serra's work *The Hedgehog and the Fox (*2000) – far right – however, these prototypes echo conventional sleeves already seen in fashion garments. The group was challenged to think of scale, to envelop the body and not merely decorate it.

Figure 12. Photo log on Instagram by student from Group C. We see the visual references to Richard Serra's work (far right) translated into pleats for the body (far left). However, the scale has been reduced and becomes almost decorative.

> "Although it was challenging dealing with the scale, one of the best things I discovered about this project is that I didn't have to construct something wearable. This kind of project helps us to generate and broad out the creativity and the ideas we have, apart from learning the technical aspects of fashion." (Kim, 2019)

The prototyping – or *toile-ing* – process required in this process also required the students to physically use their bodies for scale, as seen in the following figures. Students literally were moving differently and viewing their work from different angles while trying to anticipate the possible journeys their dancers could take. In this manner, the groups could begin thinking about dress as a vessel and enabler for movement.

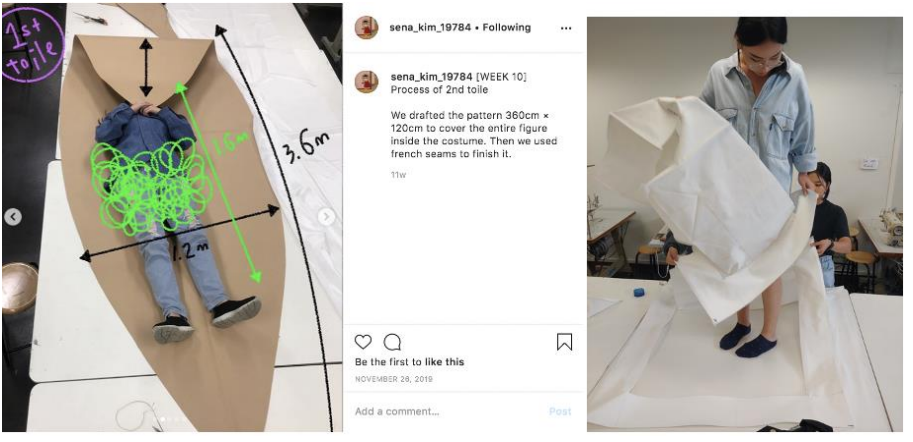

Figure 13-14. Figure 13 shows a photo log by Kim from Group C showing the scale of the garment. On Figure 14, a photograph by the lecturer shows the unusual and physical way the students took towards the construction of this garment.

It should also be noted that the dancer who collaborated with Group C was stretched clearly in her choreographic and performative norm. Not only through the dialogue with her fashion peers in decision making for the garment, but moreover in how she allowed new and playful vocabulary to emerge from working directly with the garment as another dancing body. Shifting from object, to body, to vessel, to skin and back, the choreographic work challenged the embodiment possibilities for both garment/costume and dancer. Nuance and sophistication of choices in both making and performance yielded an overall stunningly creative solo.

Figure 15-17. The garment from Group C went through several creative and technical modifications through the term as a result of a dialogue between both disciplines. The garment needs the interaction of the body to morph and develop form.

3.3 Final Performance: Beyond Garment

As the garments/costumes became finalised, the subtle shifts in garment or in solo are honed in, allowing for a further transformation into one body, rather than two. The students can view the collaboration as a hybrid of the two disciplines, forming another entity.

While many groups struggled and journeyed through different possibilities, Group D went with an initial idea that they carried through the seven weeks of the term, making slight changes to the scale and rhythm of the garment. Zulfa, one of the students' in this group, showed early engagement with the theme. In Figure 18, the initial idea was to provide a garment with multiple holes with the idea of allowing different ways of entering the garment. The scale was still too decorative and small, so the students experimented with changing the scale and material, paying attention to how the holes/gaps created forms. The results of this particular piece really stretchy the definition between dress-costume-garment-object, depending on how the dancer interacted with it.

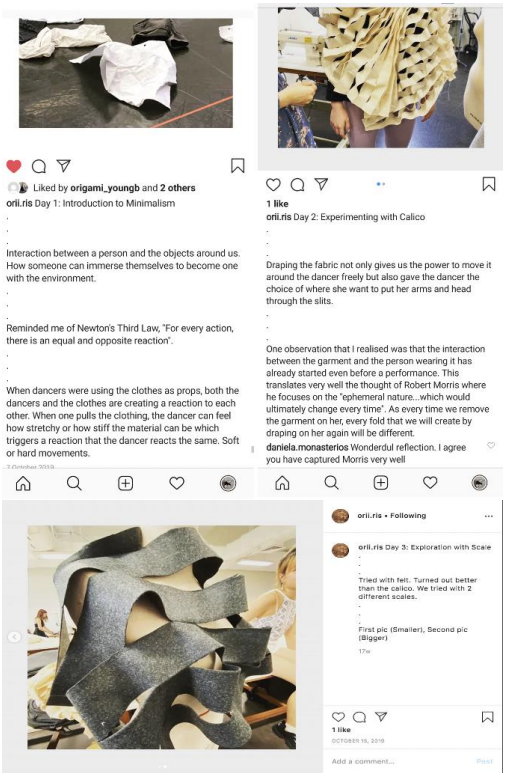

Figure 18-20. Photo log reflections from Group D shows the development of the project was smooth, and the changes made were nuanced and small—more internal and less dramatic.

The dancers, improvised and worked collaboratively with the fashion designers, an interplay of conversation between inner bodily folds and the folding possibilities inherent in the garment/costumes emerged. Form arises, but out of the exploratory internal/external movement play. In the performances, it was impossible to determine a choreographic form, shape, or style from the start or to fully 'set' or 'fix' the movement language; the solos stayed in a constant state of becoming, yielding an aesthetic through process and time.

Figure 21-25. The fluidity of Group D's garment can be seen in the choreography shown above. Group D's dancer similarly found ways to go from a traditional showing of the garment as dress by beginning to lift it up above her (Figure 21, top left), and then discard it as shell (Figure 22, top right), inhabit it as a shell/container (Figure 23, bottom) and again find different ways to wear and escape the garment.

This constant conversation of the 'choreographic making' and the needs of 'performance' opened to tone and details to shape and hold the solos. The vulnerability and surprise that each garment/costume possessed were key to the sophistication of invention within the works. They could be read and related to as another 'body', a partner/companion, each becoming a bodily extension, a nest, a container.

As the students were in process, the dancers became more aware of the necessity to yield materiality and form. Several began with a more 'aggressive' gesture and attitude towards the garment/costume, such as the dancer in Group A, but in time realised that more subtlety and a delicate lightness was needed to be embodied for the solo to be woven as a whole. Others, as in Group D, began working choreographically in a literal sense, moving in the garment/costume to reveal a more commonality of wearability. However, through the group's process, the dancer began to discover a myriad of inventive modes of dialogue, acquiring a mature and imaginative choreographic voice as the materiality and design of the garment/costume transformed into a second skin, scales, a terrain to navigate in, as well as webbed rib-like cage.

The Dance student from Group D articulated beautifully in her journal:

> " The project had challenged my creativity as the garment is ever changing due to the constant expansion of the slits and the size of the garment….I was able to morph into ideas of 'escape and release' which forms my intention…the idea of tangling and detangling, interweaving, wrapping and rolling, coming in and out of the garment, falling (myself and the garment) and of course, folding, in a sense that I would fold my body or the garment to explore and achieve the choreography."

4. Conclusion

> "To learn, habit needs a *perturbation* – a nudge to the body-context status quo. This nudge comes as a novel stimulus to the brain. It awakens and enlivens neural processes, enabling plasticity and learning. Perturbations move the perceiver away from the familiar toward new possibilities for action." (Batson, 2014, p.131)

Our personal pedagogy and way of working was also impacted in the process, as we attempted to expand the vocabulary of the project in its fourth year. After every cycle, a new set of restrictions- or *perturbations*- arose to sharpen the qualities that were important for the project: form, affordance and possibility for movement. The stripping of colour to white in the second cycle allowed for clearer shapes to arise. In the third cycle, students were introduced to the thematic stimuli of minimalism, which further abstracted their visual references. For the fourth cycle, an additional abstraction in the origami technique allowed students to prioritise play and form over attainment of the perfect technical folding technique.

The project expands not just the students' but the lecturers' pedagogic methodologies and language, providing an expansive platform for emergent creativity in design and teaching. In consultations, it was important to remind fashion students to privilege the dancer's movement over the aesthetics of the garments. To communicate with students, more bodily practices were utilised. In Figure 25, a lecturer prototypes in miniature to communicate spatial ideas to the students. In Figure 26, an example of a fashion lecturer physically inhabiting the *toile* to have an embodied understanding of its physical limits. The language of

communication of ideas extends to body/movement language and embodied understanding of design.

A somatically informed pedagogic practice stimulates greater agency and invention. Through collaborations such as this, we can begin to open the students to new avenues of making. By collapsing pre-conceived, siloed techniques and disciplines, other modalities and languages have space and support to arise.

Figure 25-26. These images show the different modalities and ways of communicating that the fashion lecturers also begun to employ. In Figure 25, a fashion lecturer utilises miniature models to communicate spatial ideas and in Figure 26, a video by a student shows a fashion lecturer inhabits one of the garments to understand the physical experience and affordance the costume enables.

About the Authors:

Daniela Monasterios-Tan, MA Fashion Curation, is a fashion researcher, curator and lecturer at LASALLE College of the Arts. Her research and pedagogy centre around de-centering fashion studies, body, materiality and aesthetics.

Susan Sentler, BA, MACP is a multimedia independent Dance artist. Her practice is interdisciplinary, anchored via a honed/expanded somatic relationship to image. Susan has lectured, collaborated, performed and exhibited in the UK, USA, throughout Europe, Indonesia, Hong Kong and Singapore.

Ginette Chittick, MA in Design, is the Programme Leader of the Diplomas in Fashion and Creative Direction for Fashion at LASALLE College of the Arts. Her practice spans music, visuals arts and design. Her current research interest is in the intersections of design, art and craft observed through the lens of aesthetics of care.

Acknowledgements: We would like to thank our colleagues at LASALLE College of the Arts, our students and the National Gallery of Singapore for their generosity, resilience and creativity.

Towards a new design culture of scientific production – Innovating the formats of scientific publication of design

Eleonora Lupo*[a], Beatrice Gobbo[a], Emilio Lonardo[a]
[a] Politecnico di Milano
*eleonora.lupo@polimi.it

Abstract | In Italy, the normative system of evaluation of the quality of scientific production and publication of design research is becoming articulated and complex. Moreover, the cultural dominance of western and Anglo-Saxon centred vision and standards need to be complemented by a plurality of approaches and narratives on design. Many trends are permeating internationally the design field, and in particular, the ones related to digital transformation. In this respect, one of the contemporary challenges that design research is undergoing is to reach an authoritative, high impact and effective scientific production. Starting from a collection of cases and practices from different disciplines which thoroughly summarizes the state-of-the-art, this paper, describes an ongoing research project aimed at innovating the design cultures of scientific production and publications, presenting the exploration of them according to a proposal of an innovative publication lifecycle. Finally, it proposes an envision of a format of scientific publication in design.

KEYWORDS | SCIENTIFIC PRODUCTION, PUBLICATION LIFECYCLE, PUBLICATION FORMATS, COMPOSING, ECOSYSTEM

1. Introduction

1.1 Background

The topic of academic publication which, although in a different way, has always played a central role in the different historical periods of scientific divulgation, today is going through a moment of profound change. Publication is central to the making of science. Epistemologically, it is a critical step in the making of publicly accepted knowledge; sociologically, publication has become the measure by which researchers are evaluated for tenures, promotions, and grants (Fyfe, 2000). Most of the features we associate with the modern scientific journal – including originality of research, self-authorship, refereeing procedures, and standardized rhetoric and structure – were nineteenth-century developments, while big profits, the use of English as the international language of science, and the emergence of professional bodies for managing editors and publishers are largely twentieth-century phenomena (Baldwin, 2018; Moxham & Fyfe, 2018). Until the mid-nineteenth century, original research could be first published in a wide variety of places. Reports of new research findings might sit alongside book reviews and letters to the editor in a magazine devoted to natural philosophy or amid discussions of philology, antiquarianism, and moral philosophy in learned journals (Peiffer, et al., 2013). By 1790, at least a thousand scientific and technical journals had been established (Kronick, 1976). Around a quarter of these were the transactions of learned academies and societies, but the majority were independent, set up by printers, booksellers, or editors with the hope of turning a profit from the learned and/or public culture of science. As before, most of the new periodicals were short-lived. But by the end of the eighteenth century, a handful of editors demonstrated that, with the right commercial skills and a good network of contacts, an independent journal could be successful (Fyfe, 2000). Recent attempts to estimate the number of academic (not just scientific) journals globally suggest that there may be around a quarter of a million – but in 2010 perhaps only 24,000 of these were scholarly peer-reviewed journals (Larsen & Von Ins, 2010). The proliferation of scientific journals has reflected the emergence of new specialisms, the establishment of new societies, the growing number of researchers seeking to build careers, and the global expansion of the scientific enterprise in the late nineteenth and twentieth centuries, but the expansion of scientific research had placed strains on these publishing programs, with more research papers meaning more expense. Elsevier and Pergamon Press took advantage of the post-war boom in science funding – including library budgets – to increase circulations of their journals and to raise the prices charged to institutional subscribers (Fyfe, 2000).

In recent years the body of design research develops and expands, and it is interesting to examine the publication patterns of institutions and researchers publishing in the field of Design. Particularly, the scientific publication in the field of Design reflects some factors related to the recent valorisation of the disciplines, but also the richness of approaches,

fields and applications combined with a proactive and often innovative attitude that design is used to propose in terms of content and visualizations.

1.2 Relevance

The digital transformation is also permeating the field of academic publication in design on a global level: the concept of *phygital* (the interaction between the physical and digital world) blurs its boundaries and research areas, introducing new ways of intervention. In this context, the scientific production and diffusion of design, especially in the international sphere, are taking on new forms and objectives, becoming increasingly unstructured, broad and, thanks to the digital environment, rhizomatic, with the related strengths (e.g. accessibility) and weaknesses (e.g. reliability).

For example, with the *Berlin Declaration on Open Access to Knowledge in the Sciences and Humanities* (2003) the open access paradigm has acquired great importance.

Paradoxically, the Article Processing Charge (APC) system of peer reviewed scientific journals (WOS, SCOPUS), increasingly recognized as a quality criterion, remains the responsibility of the authors. Meanwhile, especially in Italy, the regulatory system for the evaluation of scientific production is becoming more and more complex, due to procedures often conflicting at different institutional levels (university criteria, VQR, ASN), in a framework of actors (ANVUR, SSD scientific boards) equally varied.

These conditions have a considerable impact on the circulation of high-quality scientific production and limit the possibility of innovating its methods and formats; one of the challenges is to enable new spaces for experimentation in order to achieve authoritative, high-impact and effective communication, pursued with a multiscale strategy, which guarantees scientific productivity and extended impact (e.g. the third mission), while maintaining rigour and authority.

The European Community's Future of Scholarly Publishing and Scholarly Communication report written in January 2019, proposes a vision for the future of scholarly communication; it examines the current system and its main actors. It considers the roles of researchers, research institutions, funders and policymakers, publishers and other service providers, as well as citizens and puts forward recommendations addressed to each of them. In structuring the context of reference recalls that the whole of the scholarly communication exists to offer researchers the possibility of participating in a distributed system of knowledge that approximates H. G. Wells' vision of a "world brain", also remembering how, starting in the '80s, the whole research ecosystem has invested the metrics with great power: overall, researchers, funders, and university assessments have come to rely too much on the evaluation function of scholarly communication as structured by the JIF.

For the UE, researchers and their needs must be put at the heart of scholarly communication of the future. This scholarly communication system must support and facilitate the use of knowledge and understanding for as wide a range of participants as possible, with as wide a

range of purposes as possible, including its integration into new lines of investigation and new forms of education, according to the principles of: *Maximizing Accessibility, Maximizing Usability, Supporting and Expanding range of contribution, Building a distributed and open infrastructure, working for equity, diversity and inclusivity, building community, promoting high-quality research and its integrity, facilitating evaluation, promoting flexibility and innovation, investigate cost-effectiveness* (European Commission, 2019). In this context, the European Community hopes that working partially against this trend new technologies and services now enable researchers to take back some control over some elements of publishing, in particular registration and dissemination. They can, for example, ensure attribution to their own work by posting versions of their outputs on web-based and open access services such as an institutional repository, or a thematic repository such as *arXiv* (Cornell University, 1991). In doing so, they maximise dissemination and accessibility to their own work by themselves.

Universities have always been key actors in scholarly communication in the context of their research and educational missions, so they are both co-operative and competitive and seek to maximise the dissemination and impact of their research but, in the last fifty years, they have partially and gradually disengaged from their roles as publishers. Digital technologies, especially in their free and open form, allow them to design, maintain, evolve and control their own dissemination tools.

In this the design discipline can be a pivotal field for the experimentation and discussion of new scientific publication formats.

A recognized academic community such as the Design one has the responsibility to discuss and innovate the contexts in which scientific dissemination and dissemination are produced and made accessible, and to propose a vision characterized by its recognizable design culture.

1.3 Related work

Since it is a work in progress research project, this section does not claim to be exhaustive but simply presents the context outlined in the analysis path, deliberately excluding from this review platforms and events relevant but mainly informative (e.g European Researchers' Night) and technical-instrumental approaches: many resources and tools are available online on how to develop effective dissemination strategies, especially in relation to research findings of projects.

By exploring the digital environment many bottom-up initiatives of dissemination, addressing visual qualities and aesthetic experience can be observed, having a potential of development in term both of novelty and authority with vantages (accessibility, contributiveness…) and sometimes disadvantages (authoritativeness, reliability…).

Among the major changes that have occurred in recent decades in the field of scientific publication, the open access movement has disrupted the way scientific knowledge is

distributed. Due to excessive commercialization and price increases, Open access scholarly journals enable users from throughout the world to access information freely, as these journals can be freely accessed online without any legal, economical, or technical barriers. (Kim, et al., 2018)

The theme of new models and tools for scientific dissemination, in relation to digital transformation, besides being conspicuous on-line at a popular and technical-practical level, is widely debated in literature. As example Tenopir and King on the subject of e-journal propose "new, electronically mediated peer review models" while some scientific fields, such as medicine, reflecting on a scenario in which traditional metrics are flanked by the more recent ones of blog e social media based on the availability of sources and accessibility to dissemination channels on effective digital infrastructures. (e.g. Jama network).

A good reconnaissance is offered to us by Kim, Chung e Lee who outline a scenario according to which new formats of articles include graphical abstracts, interactive PDFs, the application of semantic enhancements, and the utilization of research data, social networking sites, such as *Mendeley* (Elsevier, 2007) and *ResearchGate* (Fickensche, 2008), have become common sites for information exchange; *altmetrics* have been adopted to complement traditional journal metrics and *PubMed Central, F1000Research and KoreaMed Synapse* have been introduced as innovative full-text scholarly journal distribution systems. With their work they have outlined a number of current trends in scientific publication which analyses new formats of journal articles (e.g. JAMA by American Medical Association and Nature Podcast by Springer Nature), ways of improving semantics in scientific publication, the use of research data and academic social networks (e.g. ResearchGate, Academia) and new distribution systems (e.g. PMC, F1000Research, Frontiers).

In this context, therefore, even the major actors are moving to try to accompany this process of change. In November 2010, Springer announced a new product line – *SpringerBriefs* (Springer, 2011)– for works between 50 and 125 pages in length. *SpringerBriefs* are concise summaries of cutting-edge research and practical applications across a wide spectrum of fields; then the following year, 2011, saw the launch of Princeton Shorts, brief selections taken from previously published influential Princeton University Press books and produced exclusively in e-book format.

In 2012 was the turn of Palgrave Macmillan, that launched *Palgrave Pivot* (Palgrave & Macmillan, 2012), an innovative format for scholarly research offering a new mid-form format for publication.

The discipline of design is relatively young but has rapidly matured in recent decades. This is evidenced by an increase in the number of design journals and dedicated design conferences since the late 1980s, and by an increase in the amount of attention being paid to design in journals from other academic fields like innovation and marketing (Gemser & de Bont, 2016). But as well explained by the authors, a particular criticality also emerges in this area: on the one (Opening Science, 2012) hand there is cultural production that can be valorized in

terms of scientific production, on the other hand there are quality content that cannot be technically valorised, but that builds reputation and identity. It is therefore appropriate to question about the new methods of production and representation of design knowledge and, above all, about overcoming the limits of exclusively textual models of dissemination, which sometimes fail to be flatly effective.

1.4 Research questions

The ongoing research project is aimed at innovating the design cultures of scientific production and publication, starting from a structured presentation of a collection of relevant case studies.

The underlying research questions concern the role of innovative practices in the scientific publication process, the identification of those stages in which the traditional practices could be released and the envisioning of communication strategies for making innovative practices techniques available to the design scientific community.

The project is based on three main intertwined hypotheses, that are:

- The lifecycle of a scientific publication is going to be more and more circular and iterative instead that a linear one (from data collection, to authoring, peer review and publication and dissemination): the co-creation and co-contribution paradigm are already established in some works, but the circulation, use of re-use of scientific contents can be further promoted and improved, maintaining authorship. For doing this, lifecycle phases need to be individuated and empowered in order to be transformed/enriched in innovative functionalities performing a multi-layered and growing publication (i.e.: sharing, evaluation, reuse etc.);
- The size of a scientific publication is going to/can change during its lifecycle(s), due to different use, re-use and contribution, allowing to add different layers of content;
- In both the above-mentioned process, *traceability of authorship* and *assessment* of contents needs to be pursued in order to maintain rigour and accreditation.

2. Methods

2.1 Approach

The research has been structured in five phases according to the main research questions.

1. The first phase of the presented research refers to the *contextualization and framing* of the problem, considering both, inquiries related to the innovation in the scientific publication process and ground-breaking case studies;

2. In the second phase, attentive scrutiny and *classification of existing innovative scientific publication formats,* coherent with the above-mentioned hypotheses, have been performed;
3. The third phase is devoted to the envisioning, design and prototype of a new format that will further develop the concept of open lifecycle and size of scientific publication in the field of design, and eventually other disciplines;
4. Finally, the fourth and fifth phases are respectively dedicated to the evaluation of the prototype and its dissemination and spreading across the scientific community.

The paper will exhaustively present the first two phases

The research involves ten researchers coming from different fields of Design.

2.2 Evaluation Matrix Design

Evaluation Criteria

The first phase, contextualisation and framing aimed at defining the common elements of innovative practices, has led the design of a shared spreadsheet where all the innovative case studies would be collected in a matrix.

Besides straightforward classification parameters such

- Title of the project;
- Year of publication;
- A brief description;
- Disciplinary field;
- Type of accreditation;
- Type of media supported;
- Format;
- Contact person;
- Management;
- List of keywords.

The size and life-cycle stages categories were introduced being those parameters themselves results of the research. The introduction of those tailor-made categories has led the researcher to classify all the case studies according to the first phase of the research.

Size

The *size* parameter refers to the dimension of the product, according to the type of elements which contains. It could be a single item, an ecosystem or a platform. A *single item* is a single, stand-alone unit with well-defined borders even if composed by a different type of media: for instance: a book, a website, an application (National Science Foundation,

2011). An *ecosystem* is an independent system of contents, with well-defined borders and structured by single and discrete units (Howard Hughes Medical Institute, 2011). Finally, a *platform* which is intended as a service of access, research, consultation and or production of contents (JoVE, 2006) (Figure 1).

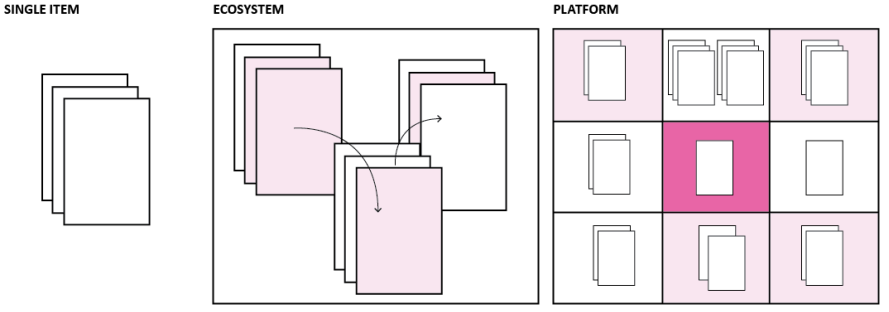

Figure 1. The size evaluation criteria.

Publication lifecycle

The publication lifecycle which is not innovative per se (Björk, 2005) is intended as a recursive chain of steps aimed at the final publication. As already introduced, the aim of the project is to transform the stages in specific processes for innovating the publication, both in the analysis of case studies, and especially in the new publication format prototype.

Indeed, during the case studies classification, the need to identify at what stage in the publication cycle the innovation had been introduced emerged; for that reason, has been added in the classification parameters.

Initially, the proposed publication life cycle included ten separate stages, which have been inferred from the analysis of the literature.

Innovation in scientific publishing at the level of exploration, means designing artefacts able to help researchers in finding articles correlated to their research interests and for some years now it has been managed by machine learning algorithms such as natural language processing which allow better customisation of interests. Moreover, some platforms allow users to save and archive material to be cited later.

At the stage of sharing, are involved platforms and websites helping users to share in-progress research. Micropublication (Micropublication, 2019) is an example such as (Cornell University, 1991) repositories which allows a direct conversation with other researchers.

Moreover, there are some examples at the connection stage, which is strictly correlated with the sharing phase. The stage of connecting refers to the dynamics adopted to connect with

other researchers. Academia (Academia, 2008) and ResearchGate (Madisch, 2008) are well-known and striking examples.

Then, especially when dealing with collaborative articles, innovative practices of writing articles are required. CodeOcean (CodeOcean, 2017) and Overleaf (Overleaf, 2014) are only two of the existing dozens.

Between the *writing* and *publishing* stage, a critical and underestimated moment is the one dedicated to the *composition* of contents. *Composing* means articulating and augmenting, giving the user the opportunity to increase the value of the research. This stage, more than the others, is crucial in the design activity. The naming itself of the stage refers to that design task which embeds the selection, structure and communication of the scientific contents.

The *publishing* stage includes all the tools and platforms aimed at accelerating the publication of peer-reviewed science. Moreover, the *reading* stage includes systems and tools which allow improving the reading experience. The annotation tool *Hypotheses* (Hypothesis, 2013) is one of those examples. The process of evaluation has been subject to innovations too, being open peer reviews increasingly common. The *re-using* stage covers tools and platforms aimed at tracking scientific contributions and ensuring that the original research is reproducible. Finally, some other cases, focus on the *innovation* of the *assessment* stage, which best practice is the assessment and check of the impact of scholarly research.

Evaluation Matrix

Furthermore, according to the ten evaluation criteria aforementioned, an evaluation matrix of case studies has been designed in order to systematically and collaboratively store the outstanding cases in the literature.

From a list of more than 400 projects, presenting innovative practices in the publication lifecycle, 50 relevant cases have been chosen as more relevant to our research, taking in consideration their level and stage of innovation, trying to cover each publication stage with a balanced number of examples.

Finally, the latest version including the most ground-breaking 20 cases has been made.

The evaluation matrix, which will be commented and explored in the Results session, will be the starting point for the third phase of the research project.

3. Results

As we mentioned above, the paper is presenting the preliminary results of ongoing research.

In this session

- The evaluation matrix;
- The updated publication lifecycle scheme;
- The *Prode* identity and the website-archive.

will be presented.

As we mentioned in the Methods paragraph, the publication lifecycle stages have been exploited for classifying case studies. The majority of the presented projects is not specifically tailored for a specific discipline or field but there are some cases such as *Jove* (JoVE, 2006), *Distill* (Distill, 2016) and *Parametric Press* (Matthew Conlen, 2019) that are discipline-oriented and very effective. By browsing the matrix (Figure 2), it's clear that the discipline-oriented cases embed innovation in the stages of *writing, composing and publishing* which lies at the heart of the cycle. Indeed, the way contents are organised, mixed, structured and augmented must be peculiar to each field of research. If the literature offers examples where ad hoc platforms have been created for medicine, biology and computer science there still seems to be room for experimentation in the Design field.

Parametric Press (Conlen, 2019) and *Distill*, are built atop *Idyll* (Heer, 2018) an open-source toolkit for writing interactive articles. Even if geared towards computer science, data visualisation and social science topics, both of them offer to the user the possibility to build interactive views and customise digital content — which is a feature to take in consideration when moving to the Design field —.

One of the main outcomes of these phases was the identification of three most promising stages from the publication lifecycle the *writing, publishing and composing* from which to start designing the final prototype. Indeed, giving the researcher the possibility to customise interactive digital content, is the stage of the publication lifecycle named *composing*. (Figure 3)

As a result of the first two phases, a website has been designed, in order to both share the research process and present the ongoing results: at the end of the research, the website will be the main touchpoint providing a framing and contextualisation of the research, an easily updatable archive of projects and the main point of access to the final prototype.

The website has been designed in order to share the results among the scientific community of the design field. For that reason, the name of the project is PRODE, which *means PRO DEsign, Scientific PROduction in DEsign.*

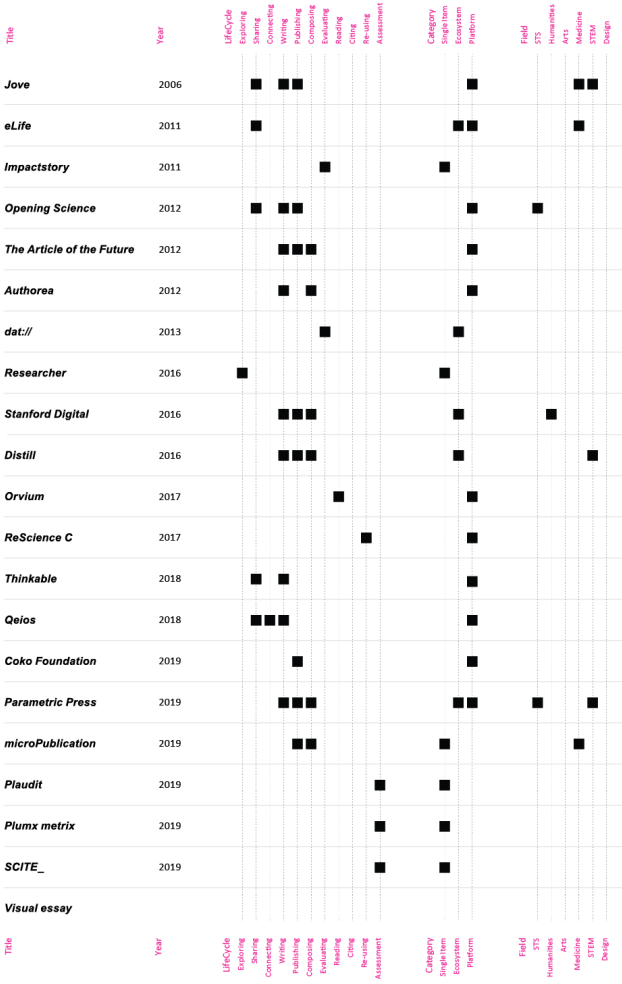

Figure 2. A matrix showing the most relevant case studies collected. For browsing the complete matrix check the website.

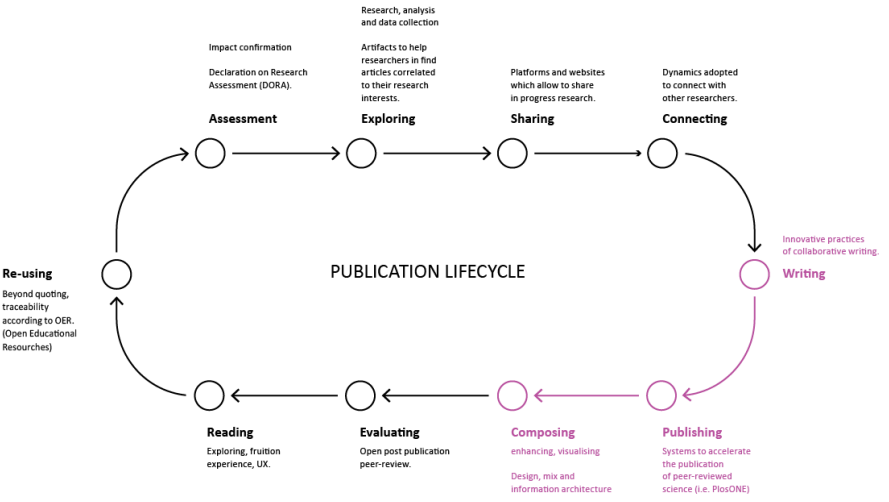

Figure 3. The publication lifecycle according to the case studies analysis. Highlighted in pink the stages of the publication lifecycle identified as promising.

Until this moment the website is structured in four pages:

- The home page: where the research project is presented;
- The about section where the produced material and the aim of the research is explained;
- The news page where activities are shared with the community;
- The case studies area, that, serving as an archive, collects and shows the analysed and relevant case studies.

In the case studies page, projects can be filtered by publication lifecycle stages through a dropdown menu. One of the most important features of the website is that the case studies area is easily editable, being directly connected to a google spreadsheet which effortlessly updates data. The spreadsheet feeding the website is organized according to some of the criteria of the evaluation matrix:

- the title of the project;
- a relevant image;
- the year of publication;
- the brief description;
- the size;
- the type of product;
- the field.

By doing so, the website becomes both *an explorative tool* and *a logbook* for the research team.

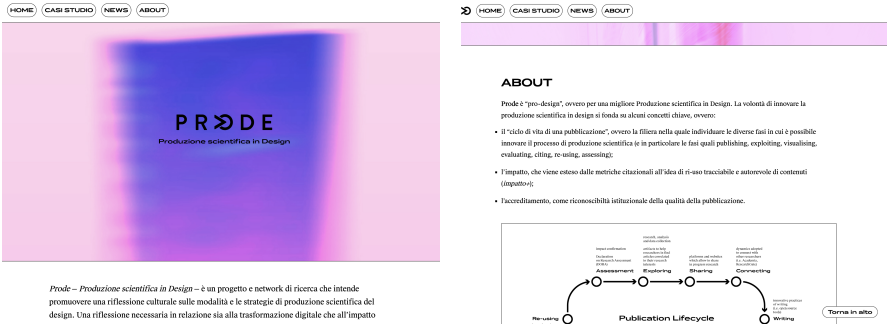

Figure 4. The Home page and the About section of PRODE.
https://produzionescientificaindesign.github.io/Prode/

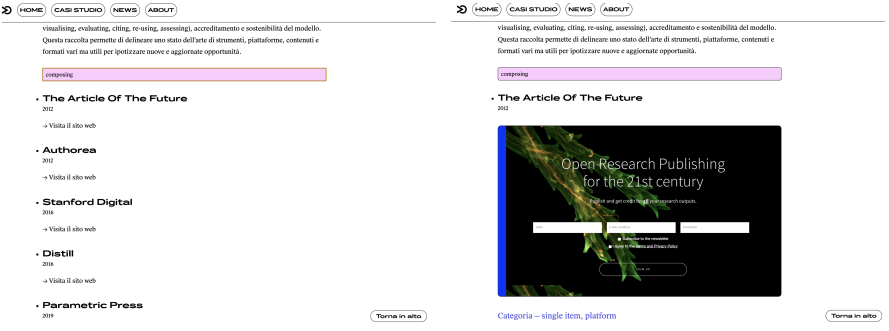

Figure 5. The case studies page. On the left a view filtered by the "composing" stage. On the right, a single case study. Users can filter data and explore single projects by reading the short description or visiting the web pages.

4. Discussion

The paper mainly highlights and distils the theoretical contribution of the presented ongoing research. The practical contribution, dealing with the envisioning and design of the prototype is still in its embryonic phase and, for this reason, it will be discussed later.

The definition of the publication lifecycle and the identification of writing, composing and publishing as the most promising stages are the main theoretical contributions of the paper. Specifically, the composing phase could be linked to common design practices and become the most encouraging one for the development of the research.

The design discipline can be a pivotal field for the experimentation and discussion of new scientific publication formats, so this is the reason why, after designing a prototype format, the aim is to have a discussion with a seminar to present the project to design-field researchers and scholars and to publishers to ask to try it and gain feedback as well first new formatted developable science.

The final output will be a prototype of a format that through scalable and implementable parameters will offer different models of visualization and units of organization of scientific content, allowing to experiment in more traditional formats, multimedia and multi-channel dissemination and sharing.

As first experiment, it is intended to draw on content already existing in the department and provided by the community itself, according to availability and interest.

Abstract | In the context of Design for health there are many complexities and challenges that designers have to face. In this paper we will analyse the main characteristics of a specific communicative artifact "the medicine leaflet". The goal is to frame it on the basis of its textual and paratextual nature, but also to reflect on its multiple critical aspects. This analytical perspective is strictly connected to Communication Design and Information Design, but more specifically to Translation Design conceived here in term of a "transformative design activity" aimed at reformulating, transferring, transcoding or, more often, transmuting a source text into a final one. Through a series of case studies, we would like to highlight the role of the translator-designer in generating new interpretations, contaminations, simplifications or expansions of content that improve the communicative access to the medicine and consequently facilitate the relationship between the various reference interlocutors (doctors, nurses, pharmacists and patients of all kinds).

KEYWORDS | MEDICINE LEAFLETS, TEXTUALITY, INNOVATION BY TRANSLATION DESIGN

1. Introduction

This paper is based on the research project *Care for care! Shaping medication to avoid treatment inaccuracy. Design culture between identity, communication and use handling* funded by the Politecnico di Milano within the University Funds for Basic Research.
The theoretical framework, defined as a perimeter for the analysis of pharmaceutical products, takes up the theoretical issues and the most consolidated methodologies of the discipline. In particular those related to the relationship between form and recognizability; form and understanding of the product; form and ease of use (affordance); those related to the interface of products and the interaction between user and product (interface design, interaction design); those related to the role of past experience and experience design; those related to perceptual aspects that activate the user's sensorial system in cognitive processes; those that refer to the analysis and design of the product based on the user (user centred design, design for all); those that focus their attention on the product-system and the product life cycle with the specific needs that characterize the different phases and the plurality of users involved; those that draw on theoretical reflections and design experiences on packaging design and on the role of info-communicative surfaces in guaranteeing access to the product (*access design*). This contribution aims at observing the package leaflet of medicines to highlight their properties, their limits and evolutionary possibilities, starting from a reading of their primary components.

2. Complexities of the package leaflet

The package leaflet for medicines is a polyalphabetic communicative artefact of a paratextual nature, which presents a serious underlying ambiguity. As Di Pace (2019, p.9) observes, on the one hand it constitutes a model of accessible textuality, while on the other it is characterised by a highly technical and specialised sectorial language, which is often not easily understood by the primary target audience (heterogeneous in terms of age, geographical origin, levels of education, and specific skills).

The nature of the medical lexicon is hypertrophic: it is in fact a linguistic system, which has become embedded over time, contaminated with other scientific fields such as chemistry or pharmacology. It presents a type-related variety of terms that can be easily accessible to highly specialised medical practitioners, but which are particularly incomprehensible to ordinary patients.

In fact, it is a matter of an articulated and hypertrophic linguistic system, a sort of "anti-language" (Calvino, 1965), whose main characteristic is the so-called "semantic terror", that is, moving away from words with a clear and comprehensible meaning, in favour of imprecise or completely indecipherable terms. The issue becomes more complicated when the users are foreigners and their understanding of the contents of the package leaflet needs to exploit a series of translations carried out by inexperienced linguists, or, in other cases,

performed with the use of computer programs; in both circumstances the risk of error is very high; indeed, there have been numerous incidents of this kind. As an example, there is the case of a Chinese woman from Prato who, due to a misinterpretation by the translator, risked killing her six-month-old daughter with a dose of antihistamine forty times higher than prescribed; or the case of a Spanish-speaking man in New York, who, owing to a machine translation, took the same hypertension pill eleven times a day, (Capuano, 2013 p.58).

This complexity is flanked by additional extra-linguistic or extra-textual issues: the readability of the written text (the size of the characters often makes it difficult to read); the information density of the text itself; the de-personalisation and absence of a hierarchy of contents (lack of emphasis on warnings and the risks that medicines entail); the lack of textual distinction (with different distribution and hierarchy) between information intended for the patient and that reserved for the doctor; the problem linked to communication media (size of the leaflet, usability and durability of the paper that is used).

Further complications arise from the numerous constraints dictated by the legislative aspects defined by the competent authorities such as the EMA, the European Medicine Agency, AIFA, the Italian Medicine Agency, the Ministry of Health or the FDA, the American Food and Drug Administration.

Given these premises, we try to understand how the package leaflet can be improved, taking into account the different types of medicines, categorized as: OTC medicines (over-the-counter or self-medication medicines with immediate visual access; also known as GSL - General Sales List); PoM medicines, which are prescription-only (and which cannot be advertised) and finally P (standing for Pharmacy) medicines, namely those not requiring a prescription, but not over-the-counter (sold on the pharmacist's advice), (Di Pace, 2019, p.32).

3. The package leaflet as text and paratext

The leaflet is also referred to in Italian as ‘bugiardino’, meaning ‘deceitful’. As de Pace reminds us (2019, p. 15) among the various explanations, the most credible interpretation of the origin of this term concerns the medical field and more specifically the recognition of the omission of a series of information concerning the negative aspects of taking a medicinal product.

More recently, as stricter regulations have come into force, the *bugiardino* has become a more articulated informative/prescribing text, in which a series of formulations remain inaccessible and scarcely interpretable to the common patient.

We can conceive of the *bugiardino* as “text”, that is, “an expressive medium capable of conveying certain content with its specific features, recognisable boundaries, and internal procedures” (Marrone, 2010, p.5). But we can also define it as “poly-alphabetic text”

because it is characterised by the coexistence of several registers, namely the verbal and visual aspects, but also the tactile aspect (when we refer in particular to the qualities of the paper).
The cooperation between verbal, visual and tactile aspects in the package leaflet requires different decoding strategies. The three systems do not operate autonomously, but support each other, transforming the leaflet into a 'hybrid textual model', directed towards reading and interpretation.

Looking at it from another perspective, the package leaflet, as a text, must not disregard its relationship with other texts that surround it: the medicinal product as the main text, the reference label, and the packaging.

In these terms the package leaflet can be better conceived as a "paratext", i.e. a text accompanying a main text, which has as its purpose the most relevant and conscious reception and consumption of the pharmaceutical product itself.

As Genette affirms (1989, p.4), the paratext constitutes a threshold, an area not only of *transition*, but also of *transaction*: "the privileged place of a pragmatism and a strategy, of an action by the public".
More in detail, the factors that qualify it can be traced back to:

1. Its *location*: the package leaflet is placed near the main text (the medicine), or is an integral part of it;
2. Its *temporal status*: it is a short-lived text, to be updated over time in terms of content, which may last as long as the life cycle of the medicinal product, or it may be worn out, lost or confused among similar things;
3. Its *substantive status*: it is itself a text, which can be characterised by several codes and different levels of iconicity, material or factual aspects that determine its reception;
4. Its *pragmatic status*: linked to the specificities and nature of its recipients;
5. The *illocutionary force of its message*: in other words, the performative power of the verbal/visual content, which may or may not include forms of manipulation of the recipient.

4. Organisation of the contents of the package leaflet

In terms of content, the leaflet is an example of "highly binding" textuality (Di Pace 2019, p.25), modelled on technical texts (such as instructions for use), which leave the recipient no freedom of interpretation or subjective assessment of the content.

Directive 2001/83/EC, supplemented by subsequent directives of 2003/94/EC, 2004/27 EC, 2008/29, constitutes, at European level, the main reference for standardisation according to the type of drug and the choices of the relevant pharmaceutical company.

A further point of reference is the European Medicine Agency (EMA), which has set up a group of experts (the Working Group on the Quality Review of Documents - QRD) for the development of the *Guideline on the readability of the label and package leaflet of medicinal products for human use* (1998, subsequently revised in 2009). The Single Medicines Commission has developed further guidelines in order to make package leaflets for over-the-counter medicines, which can be sold without a prescription, more understandable. The guidelines are flanked by initiatives launched by AIFA (validated by the European Agency EMA), which have created an institutional Pharmaceutical Database in support of citizens and healthcare personnel.

The QRD template divides the contents into six numbered paragraphs, defining them on the basis of a question/answer method:

1. What is X and what is it for;
2. What you need to know before taking X;
3. How to take X;
4. Possible side effects;
5. How to store X;
6. Package contents and other information.

It should be further specified that this is a general reference, which is subject to further amendments and specifics. It is useful to report here the indications quoted by AIFA, which, in the development of the different paragraphs, suggest avoiding the use of impersonal or passive verbal forms; the use of technical language; any reference to unclear terms; the use of abbreviations, acronyms and symbols.
Further indications suggest the use of short sentences with fewer than 20 words, and a low degree of subordination (bulleted lists); direct and active style; expressions close to the common language (technical terms in brackets); explanation of anatomical names of organs and clarifications; and pictograms alongside verbal information.

5. Graphic-visual elements of the package leaflet

The graphic-visual elements of the package leaflet are regulated by the European Commission, Guideline on the Readability of the Labelling and Package Leaflet.
The 2009 version, (Section A: Recommendations for the Package Leaflet) stresses the need to maximise the number of people who are able to use the information (by recipients we mean sighted people, the elderly, children and adolescents, those who cannot read or the visually impaired).
To this end, it invites pharmaceutical companies to recognise the specific role of designers in the visual reorganisation of content and in conducting tests aimed at gathering feedback from the target audience.

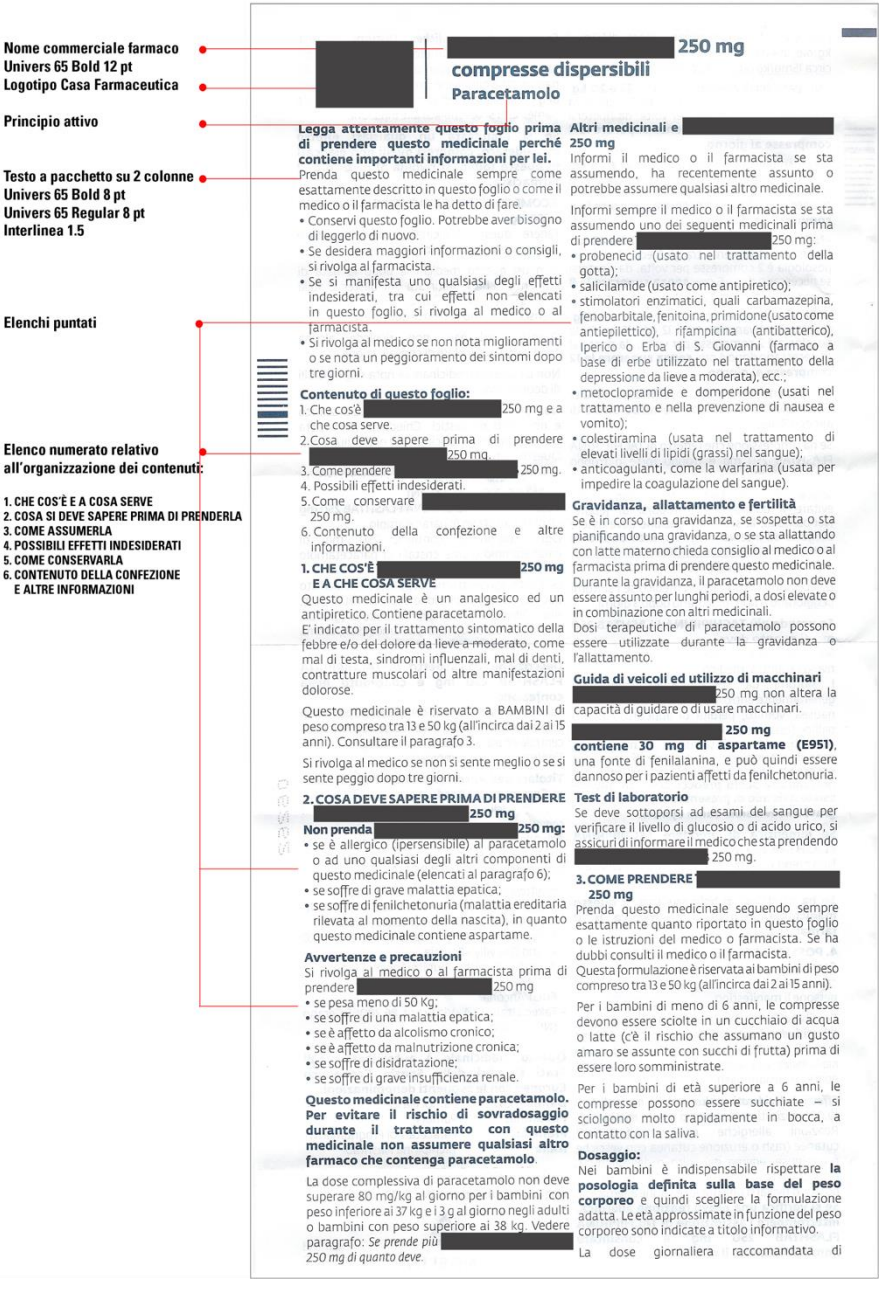

Figure 1. Structure of a medicine leaflet of a drug that does not require medical prescription.

Very briefly, the recommendations concern:

1. *Text size and typeface:* we suggest the use of readable fonts that are unambiguous when reading letters or numbers. The font size must be at least 8/9 points (as measured in Times New Roman), with a space between the lines of about 3 mm. There should be a change in size, or the text should be highlighted, to bring out relevant pieces of information (e.g. for headers). We do not recommend using capital letters or italics (italics should only be used for Latin terms);
2. *Layout and organisation of the information:* the use of a right or left flag layout is discouraged. Line spacing must be about 1.5 to ensure readability. The contrast between the text and the background is also a relevant factor, as it is decisive for the accessibility of information. The same applies to the weight and colour of the paper, the size, weight and colour of the typefaces. The use of background images is discouraged because these can interfere with the text, resulting in decreased legibility. The text can be organised in columns delimited by a space or lines in between the columns. A differentiation between columns can be useful for multilingual texts;
3. *Titling:* this can be in bold or in a different colour from the main text and must be delimited by consistent spacing above and below. Other text differentiation strategies (numbering, bullet points, colour, indentation, font and size) can be used to aid the recipient in reading the text. Subtitles may also be used if they are important for a medicinal product (e.g. information on excipients);
4. *Print colour:* typefaces can be printed in one or more colours to make the text stand out from the background; differences in size or colour make the text more recognizable and memorable. Differences in colour, or colour intensity may be used to highlight particular warnings;
5. *Paper:* the paper weight should be such that it is not transparent, which would make the text illegible, especially when it is small; even coated paper is not recommended because it reflects light and makes the information difficult to read. Uncoated paper is the best type to use. Paper folds may or may not make the contents easier to read;
6. *Use of symbols and pictograms:* the use of images, pictograms and other graphic elements is permitted, in order to aid in understanding the information, but these must exclude any element of a promotional nature. Their role is to enrich the text by highlighting functional aspects or details also reported in textual form. The use of pictograms should be tested before applying them on package leaflets because they may have different meanings depending on the cultural context.

In reality, pharmaceutical companies do not fully comply with these recommendations. As noted by Karel van der Waarde (2016, pp.73-91), their major limitation is linked to the fact

that legislators do not have an in-depth knowledge of the skills of communication designers and their ability to organize information as a whole, i.e. taking into account perceptive, semantic and pragmatic aspects that go beyond styling.

In general, there is a widespread prejudice that the communication designer is only concerned with the visual appearance of the package leaflet, and to the writing systems, in a limited manner.

According to this vision, the designer's intervention is reduced to designing only part of the information to support subsequent testing operations.

Greater involvement of visual communication professionals is desirable, in order to make the improvements that need to be made to the leaflets (beyond the official guidelines) more objective and relevant. It would be extremely useful to open up a dialogue between the various parties involved: the authorities that legislate, operators in the sector, pharmaceutical companies, and those who have the necessary skills to modernize this type of communication artefact.

6. The package leaflet and translation: recurring translation models

An initial observation and collection of case studies has allowed us to identify a series of "translation models": in some case a radical rewriting of contents and their reconfiguration, in others an evolution of formats and/or channels of dissemination. These summarise the transformations in progress and the widespread effort to make the package leaflet more functional to the needs and limitations of patients and professionals.

The reference to different modes of interpretation is inherent in the very nature of translation, but also "the inclusion of the other", beyond the pure transpositions of the meaning or signifier. Here we try to summarise the most representative models in order to offer an overview of possible interventions.

The first form of translation of the leaflets that is under consideration is *endolinguistic translation* (or reformulation or intralinguistics), namely the translation of content within the same linguistic system.

We are referring to true "rewriting", aimed at a greater clarification of some technical terms, or at reducing the semantic density of particularly complex sections. As De Pace (2019, p.112) observes, with reference to the exemplification of a well-known prescription drug, the rewritten version loses the aseptic nature of the technical information which is converted into a predicative and thematic structure in which the name of the drug emerges.

The *typographical translation* of the leaflet falls into the category of endolinguistic translation, and involves a series of rewriting operations aimed at a more rational use of the

elements of interest: print formats, the size and arrangement of text columns and images, the organisation of hierarchies of titles, subtitles and captions (macro typography), but also aspects related to micro typography, which refers to the individual elements related to the letters, the space between letters, the word, the space between words, the line and line spacing, and the text column (Hochuli, 2018, p.7). Taking these factors into account means working towards achieving greater usability and readability of the text, but also optimising page space and consequently lower paper consumption.

Through a series of tests with different types of users, David Patrick and Samuel Dickinson (2010) identified a combination of factors that improve the interaction with the leaflet:

1. A horizontal layout allows greater management of text units;
2. Shorter text blocks ensure better use of the content;
3. A reduction in text density (and therefore a better balance between the white space and text sections) facilitates reading and comprehension;
4. Breaking down the text into separate sections (e.g. between the dosage section and the side effects section), speeds up the retrieval of information;
5. Logical uses of typography, (of lists, spacing and hierarchy of text, or size of titles) are not negligible aspects on which readability and communicative access depend;
6. Highlighting parts of the text (either by using bold or increasing the size of the text), is an additional element of orientation for the recipient.

An additional project intervention is *intersemiotic translation***,** which implies the transfer of sign systems within other sign systems. This is in fact a change of code, which in the package leaflets takes the form of an extraverbal transfer into images, photographs or pictograms (Article 62 of Directive 2001/83/EC suggests that verbal forms should be accompanied by the use of illustrative images or pictograms).

The examples are notable, and equally numerous are the configurative modalities of different iconic levels: from schematic representations in black and white, to more detailed forms of representation (involving the use of colour), as well as the use of photography.

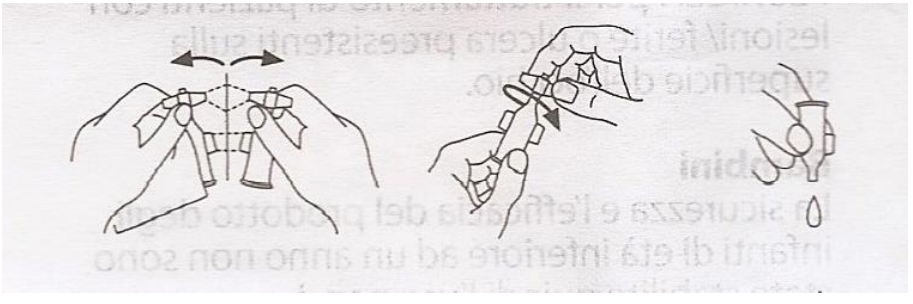

Figure 2. Visual representation of packaging use.

In terms of content, the images visually translate the instructions for use; they are found, in particular, in medicines that have complex devices or procedures for consumption, or that require specific storage methods.

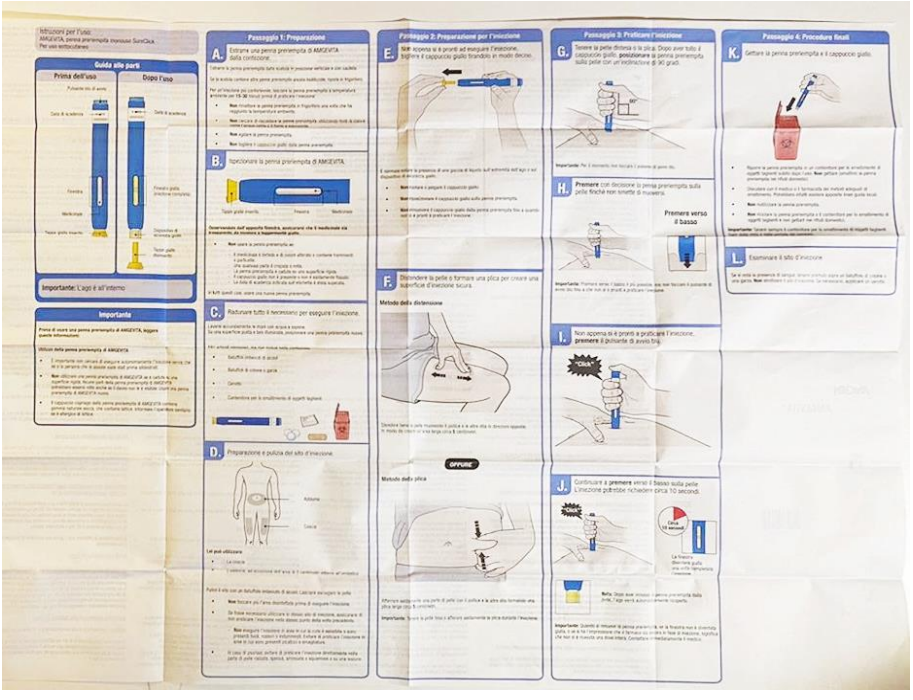

Figure 3. Visual representation of packaging characteristics and of the medicine consumption.

Other images, taking up the codes of the scientific illustration, underline the effectiveness of the active ingredients of the medicinal product; for example, by depicting the phases related to the elimination of bacteria.

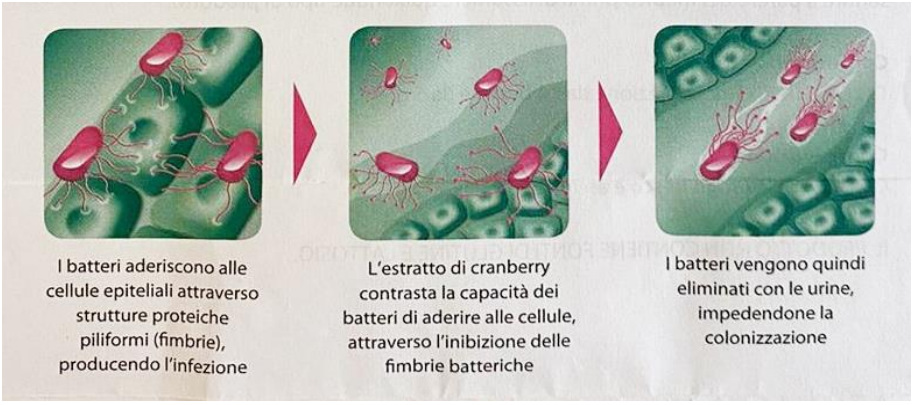

Figure 4. Visual representation of the process of elimination of bacteria.

In other cases, in particular in the package leaflets of over-the-counter (non-prescription) medicinal products, we see the use of more evocative or decorative images, or photographic images for advertising purposes to represent the different formats of the medicinal product itself.

Figure 5. Evocative use of the image.

The translation of content into pictograms is particularly significant when the reference context is multilingual, or the target audience includes: people who are not literate, the elderly, or people who are visually impaired. In general, the pictograms in package leaflets

accompany the verbal text and do not replace it completely (this is dictated by the relevant legislation).

An emblematic example is a series of pictograms designed by the American company USP (United States Pharmacopeia). Their purpose is to facilitate the understanding, storage and communication of general information, together with medical precautions or warnings.

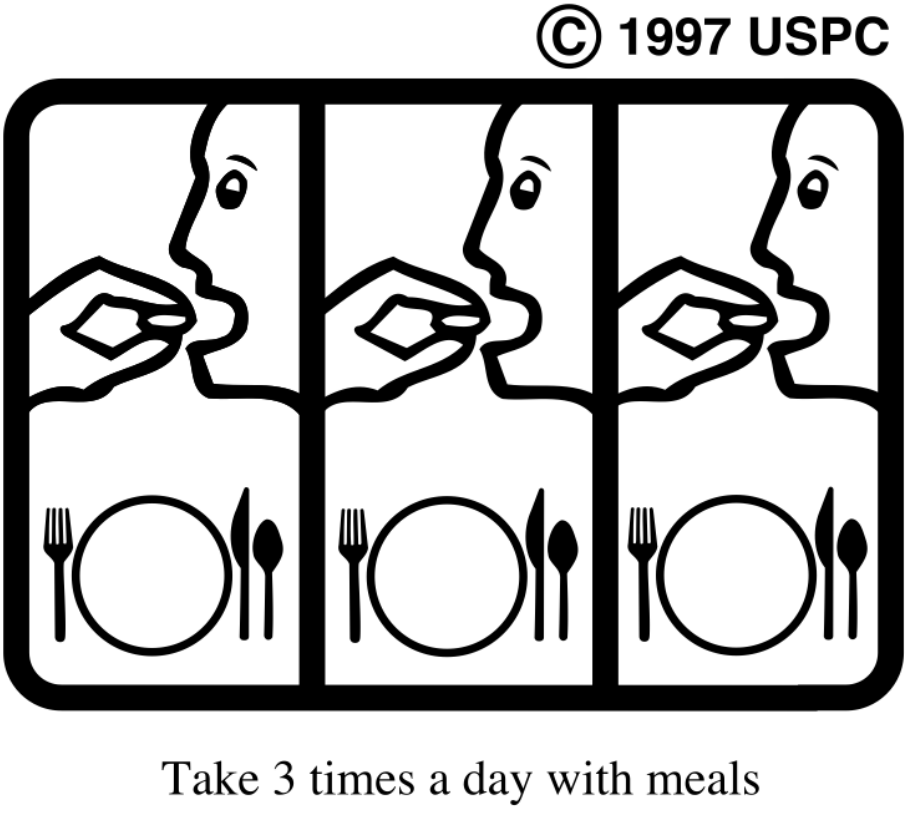

Figure 6. Example from USP pictogram system.

With reference to this project, in 2004 a Finnish research study tested USP pictograms on a category of children between 7 and 13 years of age, demonstrating their validity in terms of immediacy of communication. However, researchers stress the need for further research into the adoption of an international system of signs at European level.

Further research in South Africa tested a series of locally-produced pictograms on the non-literate population, transforming the instruction leaflet into labels to be applied directly to medicine packaging. The use of pictograms was welcomed, because it made it easier to

understand the instructions for using antibiotics. Here too, the need to raise awareness among legislators in order to promote further research in this area is reiterated.

Translating the leaflets into Braille is in fact an intersemiotic translation, because it implies the passage from the traditional alphabetical system to a coded system of symbols, which correspond to the letters of the alphabet (specifically, it is a different combination of 6 points).
The European legislation (Article 56a of the Directive on human medicines 2004/27/EC) itself states that the name of the medicinal product must be embossed in Braille, as well as the expiry date on the surface of the packaging, and suggests the availability (on request) of package leaflets or adhesive labels in Braille, for blind or visually impaired people.

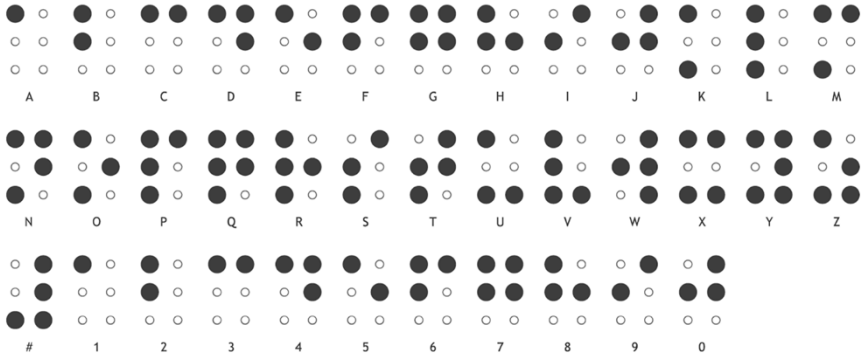

Figure 7. Pharmabraille system.

Interlinguistic translation of package leaflets should generally be entrusted to specialised professionals with high-level technical and scientific knowledge and terminology.
The need to have content translated into several languages, on the basis of EU Directive 2001/83/EC, has encouraged the practice of *inter-format translations* in the analogue field and *inter-media translations* in the digital field.

On the analogue side, given the multiplication of the contents of the leaflets, there has been an average increase of 30% in the surface area of the leaflets; on the digital side, on the other hand, work is being carried out on the transposition of multilingual contents through the use of QR codes and the design of dedicated applications.

In the first case, the change in size has led to an increase in the size of the package leaflet in width or length, resulting in a reduction in paper weight (to avoid excessive stiffness of the package leaflet), damage to the primary container, or jamming of the printing presses.

Other more innovative solutions include:

1. Leaflets folded and closed with a label or glue stitch (large printing surface but difficulty in folding them);
2. Small folded leaflets integrated into the label of the medicinal product;
3. Leaflets integrated into the case: i.e. sheets of considerable size, but folded several times so that they can be inserted into a pocket inside the package (in this case the production costs increase and the patient has difficulty in closing the package);
4. Bound sheets in a booklet format, (i.e. multi-sheet paperback or stapled booklets), particularly suitable for multilingual content and ideal for reading information and putting back into the package.

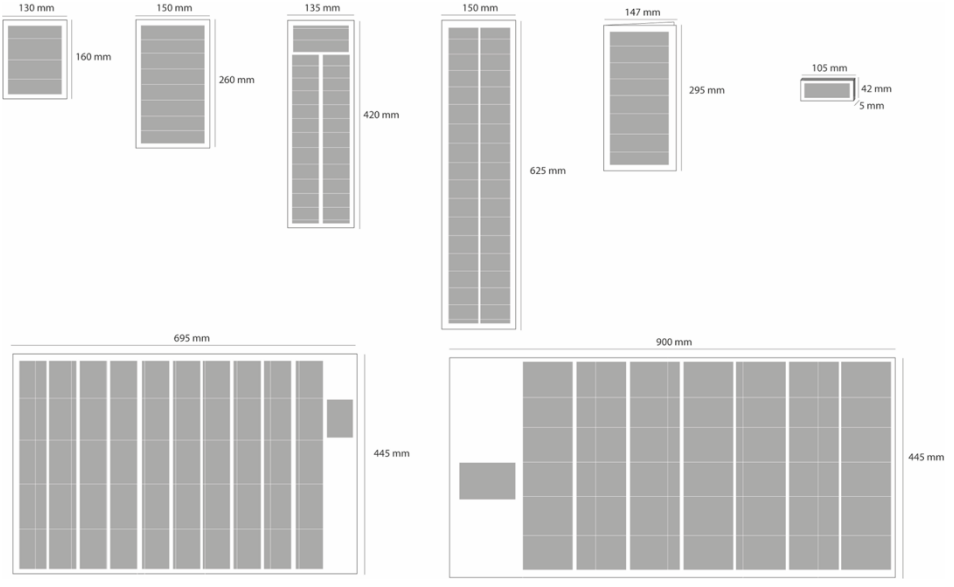

Figure 8. Different dimensions and formats for medicine leaflets.

Referring to digital, the most emblematic examples of *inter-media translation* involve specific multimodal directing practices.

In 2016 Angelini created the first multilingual leaflet (in Mandarin Chinese, Arabic, Hindi-Urdu, Russian, Spanish, English, Portuguese, German, French and Italian), the contents of which can be accessed directly from the package via a QR code (available on all self-medication headache medicines). Access through the QR code can be gained from any mobile phone or tablet enabled with a special reading application.

A further innovation is represented by "Sound Meds", created by Sifi (Società industria farmaceutica italiana) in 2015. This is an innovative audio service that allows you to listen to

the information contained in the package leaflet on your smartphone or tablet. Again, in this case, the QR code, with a large audio symbol printed on the outside of the product packaging, allows access to audio content that transmits to the patient all the information necessary for taking the medicine (alternatively the patient can access a pdf of the leaflet, which can be enlarged).

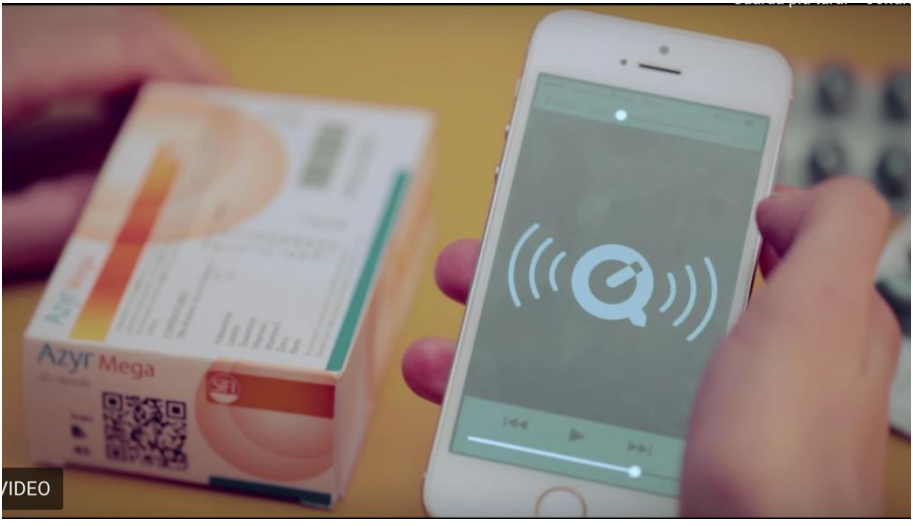

Figure 9. Sifi Sound Med system to get audio informations about the medicine.

LeggoXTe is a digital multi-platform with voice assistant that allows access to the contents of Takeda medications especially for the blind and visually impaired. This application has received the patronage of the Italian Union of the Blind and Visually Impaired (UICI) and Active Citizenship. It is available in the app version for smartphones or tablets, but also in the Google Home compatible version, for seniors who do not use a smartphone. The user can ask questions via the chatbot or with the Google Assistant, who answers the questions by reading the leaflet.

7. Conclusions

This paper consists of an analysis of package leaflets and a summary of current exemplary case studies. The aim is to make explicit a series of "translation passages" whose priority objective is to facilitate accessibility to the contents and improve the functionality of the leaflet.

We believe that a series of transformative possibilities, (rewriting, transmutations, material or immaterial transfer...), can increase the accessibility to the contents, and consequently

facilitate the relationship between the different stakeholders (doctors, nurses, pharmacists and patients of all kinds).

Referring to the translation paradigm allows us, on the one hand, to reaffirm the centrality of the recipient within the design process, (differences and specificities, interpretative skills and previous knowledge); and on the other hand, to highlight the role of the designer-translator, who has the ability to go beyond the list of basic graphic rules, and the skills to give space to improved "micro-graphic" forms of experimentation: from the experimentation of typographic fonts to the research into solutions able to optimise the use of the contents and, therefore, the efficiency of this type of artefact.

Figure 10. The LeggoXTe app makes the information contained in the leaflets of Takeda drugs available also for those who cannot read.

Visual dialects. Exploring early design sketching in various design disciplines.

Daniel Öhrling, Åsa Wikberg Nilsson

Industrial design, Luleå University of Technology, Sweden
daniel.ohrling@ltu.se, asa.wikberg-nilsson@ltu.se

Abstract | In this paper we explore the use and rationales of sketching in different design practices such as architecture, product design and graphic design. We recognise that there are preferences, manners and specific expressions that are characteristic for different practices within design, something we label “visual dialects”. Our aim is to articulate these dialects and explore the rationales behind them. The study is initiated through a literature review to explore the field of sketching in design practice, followed by a phenomenographic study of online content in the form of “how to draw like a..”. The results showed that there is a common view on why to sketch, but a differing view on how. Conclusion is that the concept of visual dialects can be a platform for furthers studies of visual communication in early design.

KEYWORDS | SKETCHING, VISUAL COMMUNICATION, EARLY DESIGN, PRACTICE, MANNERS

1. Introduction

The focus of this paper is different practices of sketching in various design disciplines. The sketch is generally seen of as one of the most elementary tools in the design process, yet there are few studies that have explored the implementation of sketching and rationales for different manners, tools and techniques in different fields. In general, there are preferences and specific expressions in most communities of practices (Wenger, 1998), which in our view are particularly evident within the different design practices of sketching. For this reason, we in this paper probe the idea of such expressions being referred to as 'visual dialects', meaning sketching having its own particular language within design, and having different dialects within different design fields. The concept encompasses manners, aesthetics and style, but also mediums, tools and techniques since it carries the language in visual communication.

According to Gleitman & Papafragou (2005), the abilities of thought and perception are the same in all humans, while language frames and filters it. In this context, language is the communication medium that creates meaning, and depending on the structure of the language, different meanings can be generated. The question is if visual expressions can correlate to language and contribute in creating frames and filters within design disciplines.

Different design fields seem to all use visual artefacts such as sketches, but have different conducts and mediums. Goldschmidt (1994) for example states expectations and contributions depends on the design culture that one subscribes to. To our knowledge there is scarce research studies concerning this. Also, Vistisen (2015) highlights that the role of sketching in visual communication is a bit overlooked in design research. For this reason, we propose a need for further explorations of the sketch and its role in design.

The overall objective of this paper hence is to explore the implementation and rationales of sketching in different design disciplines such as product design, architecture and graphic design. Drawing on a qualitative analysis of sketching videos, and a theoretical framework of sketching, communication, and sense-making in design practice, we aim to further knowledge of discipline specific visual dialects, their representation and possible effects.

2. Theories of sketching and sketches

In this paper, we define a sketch as a rough visualization that represents key features of a design, often implemented during the early phases of design. A design sketch can be described as a particular kind of drawing, different from art and drafting in its objectives, methods and values (Kirby Lockard, 1982). Also, it is proposed that "by sketching, the designer does not represent ideas held in mind /…/but creates visual displays which help induce images of the entity that is being designed" (Goldsmith, 1994 p.123). In design, sketching is generally considered the fastest method, whether you work alone or collaborate with others (Henry, 2012). In this view, a designer does not need advanced digital tools to

make a sketch, and the speed also allows for further explorations and iterations. Sketching is also proposed to have "the advantage of conveying visio-spatial ideas directly, using elements and spatial relations on paper to convey elements and spatial relations in the world" (Tversky, 2002).

In line with this, Macomber and Yang (2011) discuss sketches often being used for receiving feedback from users and other stakeholders. In this case, the sketch quality becomes important, as the medium allows or prohibits the viewer's sense making of the designer's intent. Clean hand drawn line sketches are in this case ranked highest, before both 3D drawings and other sketches (Macomber & Yang, 2011), probably because they allow for the viewer's own interpretation but still make sense.

Verstijnen et al (1998) recognize the communicative act of combining and restructuring that takes place during the practice of sketching as inextricably linked to creativity. Goldschmidt (1991) refers to this as: "seeing as versus seeing that": the medium contributes to a systematic change dialectic, through an oscillation between performance and exploration that the act of sketching contributes to. Sketching is argued to be an introspective process, providing time for reflection and eliminating the need to rely on information processing (Galle, 1992). Similar to this, Hewitt (1985) states sketches as a "medium of thought", meaning that the practice of sketching consists of both experiential and intuitive modes, which in turn may be based on previously clearly defined methodologies or instructions. In this view, in the rapid ideation sketching the visualization becomes part of a cognitive hand-eye-brain cycle, and a positive side effect of this is that others can interact in the communication through the medium. As Van Der Lugt (2005) concludes, the sketch "starts to talk", inviting people to re-interpret ideas.

The communicative aspects of sketching and sketches is multifaceted, as "the processes underlying the production of verbal and nonverbal behaviours are exceedingly complex" (Green, 2013 p.11). A challenge is that if only one aspect is analysed, the actual processes of communication might be lost (Craig, 1999). Hence, analysing visual communication by just taking the visual sensory responses into account can be misleading.

One definition of communication is that it deals with the creation of meaning (Fiske, 1990). When a sender communicates through some representation with a receiver, the medium stimulates sense making. This might be designers themselves attempting to make sense of fleeting thoughts, or clients or users grasping the intent of the design. According to Fiske, all kinds of communication require a medium, and all mediums have its own set of perceived and real affordances.

Visual communication can transmit different information compared to spoken words or written text (Jamieson, 2007), but there are differences in how different types of visual information is generated and received. In this view, there is on one hand the surface-level, in which hidden intentions are not revealed: medium and message are seen to present the

same thing. At a more profound level, visual communication can operate from the concrete (explicit) to the abstract (implicit).

A design medium can generally be described as the materials, techniques and tools used by designers to create their design. For example, a pen is a tool and ink can be the material and the technique can be how to implement those mediums to create a sketch. It is proposed that one of the main challenges in designing is keeping a lot of factors in mind, attempting to "freeze and hold constant some limited aspects of design while other factors can be thought about" (Lawson, 1997 p.242). In this view, early sketches are usually low-fidelity, and designers choose what kind of mediums to use, depending on the situation. According to Schön (1995), the need for medium corresponds to the designers' ability to see and develop a visual representation through whatever preferred medium.

The effectiveness of a medium can be considered by how well the sender can implement it, and how well the receiver can decode what the sender has intended with the medium (Fiske, 1990). In our understanding, the first phases of design sketching often seems based on the designer's own sense-making, implemented by his or her preferred medium, which through cyclic and iterative explorations and perhaps other mediums are transformed.

3. Method

The study outlined in this paper consists of a literature review and visual analysis of video material of "how to draw like a…." in different design disciplines. The literature review was implemented to collect and analyse relevant existing knowledge. The current review followed Rodgers & Milton's (2013) five-step example through initially formulating research questions to answer and from these identify areas and key words to search for and identifying sources based on academic databases such as Scopus, Web of Science, and Google Scholar using search keywords such as "sketching, visual, dialectics, communication, design, techniques, mannerism, early design" in different combinations. In order to evaluate the literature, references with most citations were chosen. Relevant aspects in relation to the research questions were then identified and summarized in this paper.

In addition, visual analysis of videos of "how to sketch…" in different design disciplines was performed. Five videos or blogs were selected from each field. The videos were identified through searching primarily Youtube (www.youtube.com) and the web using search terms in the form of "draw like a product designer", "sketching for graphic design" and similar forms. Selection were based on view count and popularity. Some search results were omitted if they did not display the act of sketching, or if they had the same author. For one of the fields, graphic design, there was too little video content available so there the search had to extend to text based blogs. The sources are listed in Table 1. The rationale behind the choice of material for the study was that we wanted to see what was communicated from professionals to aspiring designers, before they even applied to higher education, thus contributing to the reinforcement of the culture of the practice.

Table 1. List of analysed videos and blogs sorted by field.

The videos were watched and analysed by adopting a phenomenographic approach. This a way to find variations in a context and identify the underlying factors that enables them (Adams et al, 2011). The analysis is performed iteratively, going through the material, sorting it into distinct categories of how to understand and experience the context. The relationships of the different emerging patterns are explored and described.

Phenomenographic analysis is in general based on material from semi-structured interview protocols, but the method was here applied to the material at hand. To aid the visual

analysis, one of the authors undertook what might be defined as experience prototyping (Buchenau & Fulton Suri, 2001), in the sense of imitating the different sketching practices that was introduced in the videos. The rationale for this was searching an embodied understanding of the sketching practices' enactment of mediums, space, lines and other representations. This is further described in up-coming sections.

4. Study of online material

The upcoming sections outline the results of the analysis and the experience of prototyping the video material of "how to draw like a…." in the design disciplines of product design, architecture and graphic design. A first comparison between the instructional "how to draw like a.."- videos and blogs showed that there were differences in how they explained the sketching activity. The basic assumptions about why to sketch were similar independent of the field, i.e. that it was a fast tool for ideation and communication of early ideas. Though, when it came to the more communicative sketches, differences in rationales emerged..

4.1 Categories

In the analysis, three main categories were identified. The first category is the *mediums*, the tools and materials displayed in the videos. A demarcation was made for the tools used to put mark on paper, which means that drawing aids were excluded. The second one is the handling of *space*, involving perspectives, forms and context. The third category is *line*, outlining how a line is drawn through a technical and aesthetic perspective.

4.2 Mediums: tools and materials

In the graphic design videos and blogs, the tool was a pen. There was no motivation for the use of this tool, and it seemed as it could be any pen or pencil. The materials were plain paper, mostly graphed. The product design videos had a more confined tool box compared to the architecture videos. The tools used for product design were pens and markers. Also white gel and coloured pencils, they were never used directly in the videos but shown in examples. The material used were mostly copy papers and sketch books.

In the architecture drawing videos, the tools were more diverse and consisted of pens, pencils, sharpies, fine-liners, markers, brush tips. The most dominant tools were black and some coloured pens and fine-liners, and grey-scaled or coloured markers. The materials were copy paper or sketch books with dotted or Kraft paper, and tracing paper. In summary, the different mediums can be visualised as the tool boxes for the different design disciplines, containing of different tools and materials, illustrated in table 2.

Table 2. Illustrating mediums in the different design disciplines based on the videos.

	TOOLS	MATERIALS	TOOL BOXES
Graphic design	Black ball-point pen	Paper, plan, graphed or dotted	Small, but can contain whatever mediums
Product design	Pens, markers, white gel pens, colour pencils	Copy papers, sketch books	Medium, restricted to certain mediums
Architecture	Pens, pencils, colour pencils, sharpies, fine-liners, markers, brush tips	Copy paper, sketch books graphed or dotted, Kraft paper, tracing paper	Larger, less restricted to certain mediums

4.3 Space: perspectives, forms and context

The analysis of the product design and architecture videos showed that both used theories of perspectives. Still, there were a difference in how the description of proportion was valued, and the reliance on rules. Whilst the architect videos in many cases used isometric-, planar- and 2-point perspectives to ensure proportions, the product design videos more often assumed perspective using a primitive that appeared to have some sort of perspective and intended proportions as guidelines for the rest of the sketch. It seemed that as long as the lines appeared to converge somewhere, without any construction lines to see that it actually did so, it seemed fine in these videos. The space aspect was treated somewhat differently in the graphic design videos, what we propose is due to working in a 2D instead of a 3D space. The space in these graphic design videos was understood as the interaction of content on a surface, the balance, contrasts, negative space, the reading order and visual clarity.

Table 3. Illustrating the different uses of space in the design discipline specific videos.

	PERSPECTIVES	FORMS	context
Graphic design	Not applicable	Mostly squared shapes as placeholders for content	The layout of the surface involves a constant evaluation of context, placement and reading order
Product design	Assumed 2- and 3-point perspective through guidelines	Basic primitives like a box or cylinder, or combinations, form a base structure for refining	Focus is on the artefact, context non-existent or arbitrary
Architecture	Isometric-, planar- and 2-point perspective	Basic primitives like a box or square, or combinations, form a base structure for refining	Same attention on the artefact, but more attention to the interaction with the surroundings

4.4 Line

By experimenting with different types of lines showcased in the video material, distinctions could be made between line characters. The lines used in the videos for product design are in general continuous and fast, as described in video P4, see table 1: “you want to show your confidence, like you know what you are doing.” (23:55). Drawing the line becomes more of a movement than a controlled process of getting the pen from point A to B. In many of the product design videos this is promoted as something important, i.e. to practice the movement of the arm to generate fast lines, arcs, circles and ellipses.

Generally, the architecture videos show a bit different type of lines compared to product design. These lines are also continuous, but employed a bit more meticulously, slower strokes that give them a bit more wavering, but more focus on keeping the symmetry. According to video A2, see table 1, the “waviness” should support in making the lines look straighter (3:10). In video A1 it is stated that “wavy lines generates an imperfect, sketchy feel” (3:00) which is stated as a good thing. Also, video A3, see table 1, promotes “wiggly” lines, since forcing straight lines takes too much energy and focus from the aim of the sketch. The graphic design videos have a much smaller sample, and much less expressed consensus regarding drawing techniques. The quality of the line is not discussed in these videos, and areas are drawn by tracing the pen around it.

To acquire an embodied experience of how to draw like a graphic designer, product designer and architect, one of the authors made a lot of sketches based on how the implementation of lines were communicated and showcased in the videos. A result of this was the understanding of speed. To illustrate the different kind of lines used, they were organized based on speed, see figure 2.

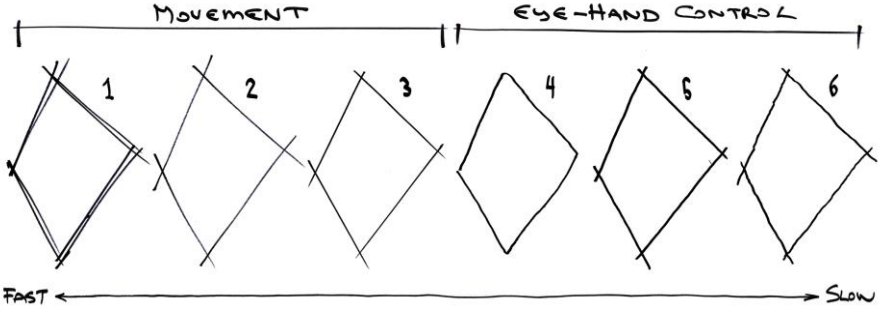

Figure 1. Visualising different lines, from fast to slow. Illustration: Daniel Öhrling

The embodied experience was that faster lines require a feeling for the movement of the line, while the slower ones require that the eye controls the movement to make sure that the tool got the right input. It was experienced as easier to draw straight lines by lowering the speed. This is of course a matter of practice, but for a moderately skilled sketcher the

fast lines never managed to get the same straightness as the slower and stricter lines. This is simply illustrating the embodied experience and conclusions cannot be made based on this experiment.

However, the findings could be displayed in a matrix using two axes: fast to slow lines, and approximate to precise. The approximation in this case means that a line only describes the character of a shape instead of depicting it in its final form, while precision is a strive to keep the lines truer to the geometry it should describe. How the measurable material from the design disciplines relate to these units of analysis is shown in figure 2. Note that the measure for graphic design is highly uncertain since there was not enough input to build upon. The plot shows that product design lines ended up in the fast/approximate quadrant, graphic design in slow/precise, and architecture also here showed a larger variety, but leaned towards slow/precise.

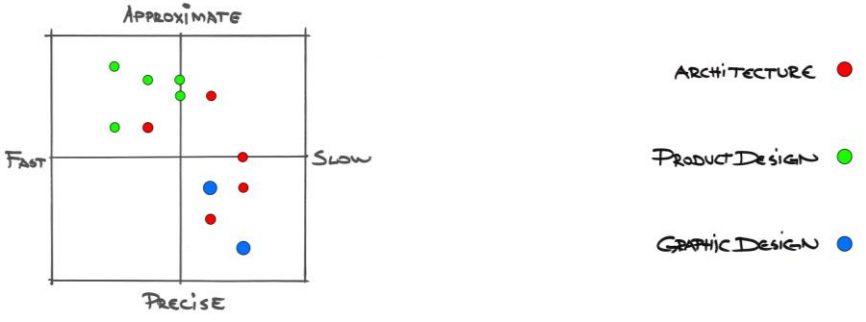

Figure 2. Illustrates the design disciplines use of lines.

The act of putting lines on the paper showed to be the largest divider between disciplines. The architects slower, careful and lively lines do not only have another aesthetic than the product designer's fast strokes or the graphic designers searching trace lines, it also appeared to give a different interaction with the lines. The faster strokes required a feeling for the movement of the line, emphasising the fluidity more than precision, and works well with broad, quick strokes. As described in for example video P4 (22:25), see table 1, the line is placed by aiming for the end destination of the line, modifying the movement depending on what curvature that is intended for it. The focus is on the intended line, not the placement of the pen. The slower lines required more eye-hand coordination and control. One had to visually evaluate the lines behaviour and adjust the movement if the line didn't go where it was supposed to. This might be the reason why the "wiggly" lines where encouraged, since the irregularity of the line conceals corrections that are made during the strokes.

5. Discussion

When someone aspires to become part of a design community of practice, it probably seems natural to conform to the discourses and expressions that the practice conveys. Watching the videos and blogs used in this study was a way to see the phenomenon from the aspiring designer's horizon, i.e. what they are confronted with when forming themselves into what they want to become.

We started out with proposing that there are specific manners and methods that are characteristic to different disciplines within design, something we call 'visual dialects' in design, and asked why these manners exist and how they might be identified. For future work, we are also interested in finding out if these dialects affect ideation- and communication space since the manners and techniques used shapes our language, and what meaning that is formed. Another question is how the conformation affects the community of practice and it's culture, and if it needs to be challenged.

The mediums used in the analysed material showed that product design had a much more limited arsenal compared to architecture. The impression is that you need a pen, some fine-liners and markers to have the prerequisites for product sketching, while there is a bit more freedom of choice when it comes to tools for architectural sketching. In one of the videos it was argued that "design sketching is specifically designed, to be able to sketch products very efficiently and quickly" (P1 (2:46), see table 1). Such statements make it difficult to argue against having to learn the manners and techniques promoted in the videos, if one wants to become a product designer, and might be contributing to the conformity regarding tools. No such statements were made in the other disciplines. In architecture, mixing up tools, mediums and techniques was promoted, as an example in A2 (5:50, see Table 1).

How perspective, forms and balance were treated differed, but mostly between graphic design and the other two disciplines. The architect- and product design videos all have a strong reliance on perspective rules, product design have a bit more "laid back" attitude but basically, they all seemed to regard it as something fundamental. Graphic design videos do not mention this at all.

The differences between how product design and architecture approach the line might be because of the object of their designs and their process. The object for architects are buildings, buildings are expected to have vertical walls, straight angles and specific dimensions for exteriors and living spaces. In their process, as it seems from the analysed material, they have a tradition of working with tracing, building on earlier drafts and drawings. This combined requires a higher precision in where the lines are placed, to make sense. Product designers work with conceptual artefacts with less specified shape, and often lines and surfaces requires tension and curvature. This seems better suited for the fast aim lines that describes the sense of curvature more than the exact placement of it.

The evaluation of the "how to.." material indicated that there were a common view regarding the usefulness of sketching in all disciplines, but differences in their views of how.

Of the three, graphic design deviated the most in this regard. The study did not give a clear answer to why. One could speculate that this is because of that graphic design works mostly in a two-dimensional space, whilst the other two works in three dimensions. Another factor could be that the graphic design process doesn't rely as much on communication of rough ideas and concepts as in architecture and product design, and therefore haven't formed a consensus around what could be described as a "graphic design style sketch". To answer this requires a different kind of study.

In conclusion, the results show that there is a foundation of techniques and methods shared between different disciplines, but also strong discipline specific biases regarding mediums, techniques and manners that may be articulated as visual dialects. Even though this study only looks upon just a small part of what can constitute visual communication, the concept of visual dialects can be a platform to explicate the character of sketching and visualisation, which can form a base for further studies on rationale and implications of how visual artefacts are generated, channelled and perceived.

Abstract | Foreign Direct Investment (FDI), or controlling investments that cross national borders, is in many respects the backbone of globalization. However, a considerable part of it is composed of "paper" shell companies used for tax avoidance and other purposes. While it is possible to reconstruct chains of FDI positions, it is difficult to raise public awareness of the full scale and shape of the phenomenon, in terms of not only the countries or amounts of money involved, but also the high levels of uncertainty surrounding estimates of these figures. In this paper we introduce the Atlas of Offshore, a visual exploratory tool meant to enable domain experts and broader publics to explore offshore finance, with a focus on clearly showing the complex webs of relationships between countries involved. Starting from a variation of the "Sankey Diagram", we propose a solution aimed at representing the topology of the network, the estimated size of investments, and the uncertainty surrounding these estimates. A prototype of the tool has been developed, testing the visual model with data describing the network of offshore investments for nine countries, enabling domain experts and others to obtain a new perspective on this issue.

KEYWORDS | BUSINESS AND FINANCE VISUALISATION, FLOW VISUALISATION, AESTHETICS IN VISUALISATION, UNCERTAINTY VISUALISATION, GRAPH/NETWORK DATA

1. Introduction

In this paper we describe the preliminary results obtained in the design of a visualization tool facilitating visual exploration of offshore financial relationships. This was undertaken as an interdisciplinary collaboration between an economic geographer, two information design researchers and two researchers with a background in media studies and science and technology studies. The working prototype, described in this paper, can be found at this link: https://offshoreatlas.publicdatalab.org/explorer.

The starting point is the economic geographer's work constructing a novel database of the estimated offshore investment relationships between specific countries. The construction of this very large network database raised an issue; namely, how to represent “complexity without spaghetti”, or, in other words, render the structure of relationships intelligible, rather than simply overwhelming. At issue here is not simply the analysis of the database, but also the question of using creative visualization tools to render complex economic phenomena legible to a relatively broad societal audience.

The visualization techniques deployed here represent an attempt to strike a balance between across two key dimensions of tensions. Firstly, as noted above, there is the desire to show both the detailed structure of international economic relationships, and the key “big picture” elements of these relationships. Secondly, and just importantly, however, there is the desire to both show our best-available current understanding of these relationships, and the willingness to avoid creating a false sense of certainty potentially shutting down public conversation (Latour & Weibel, 2005)surrounding what remains, even with the application of novel estimation procedures, a fundamentally opaque and poorly understood element of the world economy. What is particularly crucial to convey here— and what is currently not well-recognized by even many expert—is that the massive scale of the offshore data “black hole” at the heart of the world economy means that we do not really understand even many of the most basic contours of the shape of the latter (Damgaard, et al., 2019). Indeed, as Maurer (2008, p.160) puts it, “Far from a marginal or exotic backwater of the global economy, offshore in many ways is the global economy.”

Not surprisingly, these are not new dilemmas, and we can thus specifically situate the atlas project against broader debates around the knowability, unknowability and governability of transnational economic activity (Slobodian, 2018); the infrastructural configurations of relations between markets, states and citizens (Roberts, 2010); and the need for data practices that fully respond to and reflect uncertainty (Anderson, 2018).

1.1 Foreign Direct Investments

Foreign Direct Investment (FDI) consists of controlling investments by companies and individuals that cross international borders. FDI is often considered to be the backbone of the global economy, as it is created whenever a company makes cross-border investment in a factory or other facility or acquires or merges with a company in another country.

However, FDI also consists largely of “paper” shell companies used for tax avoidance and other purposes (Haberly & Wójcik, 2015). In fact, data from the International Monetary Fund (IMF) show that this offshore component of FDI —which is generated as a by-product of tax avoidance and other offshore games— may actually be larger, in total, than the amount of FDI that is not in some way linked to or distorted by offshore structures. As of 2016, roughly two thirds of all worldwide FDI recorded by the IMF —likely accounting for at least 40% of the underlying capital invested (Damgaard, et al., 2019)— was either in or from "offshore" jurisdictions whose investments are believed to consist largely or mostly of foreign-controlled shell company structures.

1.2 Dataset

Growing awareness of these problems among researchers and statistical agencies has led to a concerted effort to shed light on the contents of the offshore black box at the heart of the global FDI network. The OECD has begun to coordinate efforts by major developed economies to compile information on the ultimate, rather than just the immediate origin of FDI entering them (Damgaard & Elkjaer, 2017).

Ongoing Country-by-Country-Reporting (CBCR)[1] and beneficial ownership reporting reforms at the national and international level hold the promise of further improvements in official data (Wójcik, 2015). At the micro (company) level, databases such as Orbis[2] have opened the door to efforts to reconstruct our picture of the global shell company network from the “ground up” (Garcia-Bernardo, et al., 2017) while statistical methodologies have been applied to macro-level data to infer the structure of parts of the network that cannot be directly observed (Casella, 2019; Damgaard & Elkjaer, 2017; Haberly & Wójcik, 2015).

The dataset is the result of a methodology (Haberly, forthcoming) based on multiple micro (Orbis) and macro-level (OECD, IMF, and US BEA) datasets. It allows us to construct a multidimensional matrix of offshore FDI positions, cross-disaggregated across ultimate home country and two different layers of conduit jurisdictions,[3] in nine major economies. Each country can, therefore, have four possible roles in the network, sometimes simultaneously:

1. **Source:** “true” ultimate investing country;
2. **Secondary conduit:** “ostensible” ultimate investing country (i.e. reflecting offshore incorporations/inversions at the parent company level);
3. **Primary conduit:** immediate (conduit) investing country;
4. **Target:** destination country.

[1] to foster tax transparency OECD required all multinational enterprises to provide the global allocation of their income, taxes and other indicators of the location of economic activity.

[2] Orbis is Bureau van Dijk's flagship company database.

[3] FDI Positions are the cumulative value of investments at a given point in time.

The dataset simultaneously highlights where international investors/multinational firms claim to be based and where they are “really” based, as well as the jurisdictional pathways that they use to invest in particular host economies. The dataset is structured as independent networks based on nine destination countries that encompass more than half of the world economy: United States, Russia, United Kingdom, China, Italy, Brazil, India, France and Germany.

The constructed dataset contains a high level of uncertainty. As argued (Damgaard, et al., 2019; Damgaard & Elkjaer, 2017; Linsi & Mügge, 2019), official economic statistics and FDI statistics in particular, are far less reliable, and have much larger gaps than is often assumed. In this case, the lack of official data on offshore investment chains has made it necessary to estimate the value of these chains through a Monte Carlo simulation approach, which generates a very large number of possible scenarios of what the structure of these chains could be based on a mixture of known (fixed) and estimated (variable) data points fed into the simulation. The dataset thus does not consist of individual estimates of the value of investment positions, but rather a “cloud” of investment probability distributions, which may be wide or narrow for any given investment chain.

2. Related work

Although there is a long tradition of exploring public finances with information graphics (Gray, et al., 2016), it appears that public spending has featured more prominently in such projects than taxation or revenue (Gray, 2015). Offshore finance has been covered by journalistic media reporting specific cases of scandals that represent a portion of the phenomenon. Recurring visualization strategies include scrollytelling with data, for example “Swedes in Paradise Papers” (Hjalmarsson, et al., 2017), and explorable network graphs, mostly ego-networks (Freeman, 1982) and detecting key players (Bounegru, et al., 2017), for example in “The Power players” (International Consortium of Investigative Journalists, 2016). The project “Swedes in Paradise Papers” describes Swedish people involved, representing them by dots that are clustered according to demographic characteristics. In “The Power players” case, the stories focus on evidencing the relationship between individuals and entities, filtering leaders and politicians according to countries and world regions. A non-journalistic case is the project “How complex are corporate structures?” developed by the NGO OpenCorporates (OpenCorporates, 2013) that relies on geographical representation to show the connections and location of offshore companies related to the seven main US banks. The result is a deformed map that visualizes only the offshore companies through points, showing the financial geopolitics of world offshore "hubs". Much of the coverage associated with such leaked databases has focused on the role of specific actors (e.g. politicians, celebrities), countries, or the story of the leaks themselves, rather than what they can tell us about the structure and transnational dynamics of offshore finance. Meanwhile, in an academic setting, the CORPNET research group has produced more comprehensive (albeit static) visualizations of the structure of the global financial

networks (Garcia-Bernardo, et al., 2017) using conventional network visualization tools such as Gephi's ForceAtlas2.

3. Design approach

The dataset consists of investment relationships that pass between countries via layers of other jurisdictions. Each relationship in the dataset can be seen as an investment chain comprising all successive steps from the country where an investment originates to the destination one. Each chain can represent a direct investment from the source to the destination country, or indirect investments involving one or two "conduit" countries between the origin and the destination.

By aggregating these chains, the underlying topological structure is composed of countries (which are the nodes) linked by investments.

Two countries can therefore be linked by several kinds of investments. In other words, countries may assume different roles according to the links they have with other countries in the sequence of how the investment goes through including ultimate origin, primary (parent company-level) conduit (e.g. for offshore corporate "inversions"), secondary (subsidiary-level) conduit and destination. The main problem posed by this particular data structure is what visual model should be used to represent such a multilayered, as opposed to simply bilateral, network structure.

3.2 Design requirements

The data structure brings three main problems in the visual model design. Each country can have simultaneously multiple roles: for example, being source for some investments, and conduit for others, or either target (Figure 1). Furthermore, investments chains can be aggregated or disaggregated between each pair of nodes. Finally, these structures can easily involve loops among countries, which in practice tend to dominate the figures due to the pervasiveness of offshore "round-tripping" (Haberly & Wójcik, 2015).

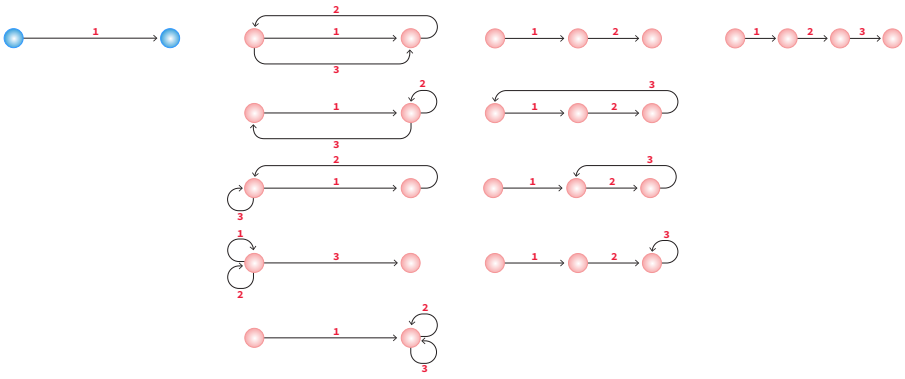

Figure 1. Diagram showing how investment chains could aggregate or disaggregate among a set of countries. Blue color chain is a direct investment while other combinations are indirect.

The described prototype has been created with the goal of representing in an efficient way to allow the database creators to disseminate results.

After discussing with the database creators, we identified the following design requirements:

- **R1.** Provide an overview of all the investment chains related to a specific country;
- **R2.** Show all the kind of chain couples (source to the primary conduit, primary to the secondary conduit, secondary conduit to the target, primary conduit to the target, and source to the target);
- **R3.** Highlights chains passing through conduits, rather than going directly from source to destination;
- **R4.** Enable the aggregation of chains passing through a group of countries;
- **R5.** Enable filtering of chains passing through a group of countries;
- **R6.** Show the value of uncertainty;
- **R7.** Show the amount of investments related to each flow;
- **R8.** Show the total amount of investments positions for each country;
- **R9.** Show the proportion of investments per country role (source, primary conduit, secondary conduit, destination);
- **R10.** Show flows directions.

3.2 Visual model design

Being a graph structure, the first tests entailed adopting a network diagram. This visual model provides an overview of all the investments targeting a specific country (R1) and would easily allow aggregation and filtering operations (R4, R5). This was indeed the first solution adopted by the database creators to represent such data.

However, the dataset is not simply composed of bilateral links between nodes, but rather by chains of links through layers of nodes. This means that the same pair of nodes can be linked by several flows following different directions. Furthermore, a conventional network diagram is not efficient in representing the different role that a country could have. It creates visual ambiguity about the nodes' sizes (i.e. the role in investment that this refers to) and make it difficult to automate node positioning due to the complexity of link chains.

In the current case, nodes are more likely conduits through which the investment chains pass. The same investment chain could pass twice through the same node in some situations, and the same node could play different roles in different chains.

Among network representations, we focused on the Sankey diagram for its ability to represent transfers or flows within a system (Schmidt, 2008). The model is usually composed of rectangles to represent the different nodes of the system and ribbons to represent the flows. The model keeps most of the advantages of network diagram and is more efficient in representing relative proportional breakdowns among flows and nodes (R7, R8). By using vertical bars for nodes, it allows to clearly show the total size of investment positions in a country as the height of the bar is proportional to the thickness of lines entering it.

Representing the nodes as bars helps visually differentiate between the roles played by each node (R9), through use of groups of stacked bars. Conceptually, each node in the diagram is in fact a group of nodes (one for each possible role in chains of investment) and therefore is possible to show how each pair of nodes is connected. For example, the node representing Netherlands in the network of investment entering the UK (Figure 2) is actually composed of three sub-nodes): Netherlands as a source, as primary (parent company-level) conduit, and as secondary (subsidiary-level) conduit, within any given chain of investment in the UK. Each of the sub-nodes can have both inward and outward investment links to any other sub-node.

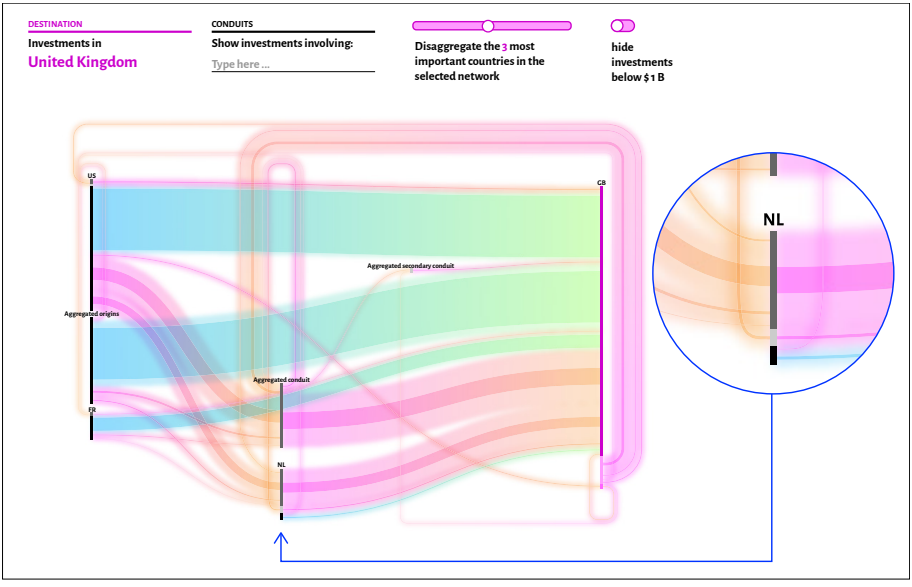

Figure 2. Example of a node with multiple roles: in the UK network, the Netherlands act as source (black bar), primary conduit (dark gray bar), secondary conduit (pale gray bar).

Through initial graphical tests, the arrangement of nodes in space (both the horizontal and vertical positioning) emerged as crucial in communicating the main role of each country. The automated layouting, as the one present in the D3.js code library adopted in the prototype (*D3/d3-sankey*, 2015/2020), was not efficient due to the large number of links among nodes: in the test, users were confused about the meaning of nodes' positions. To define a common positioning model, and to consistently highlight the role of each country in the network (R9), it was adopted a disposition based on the total amount of investment per type.

The value of all the investments passing through a node are aggregated by node role, and the most important role for each country (in terms of amount of investment) is used to define the position of nodes from left (predominantly sources) to the right (predominantly targets). Vertical node positioning doesn't encode any information and is simply optimized to minimize figure overlaps.

Finally, we designed the visual attributes of links. Two main pieces of information are shown here: the direction of investments (R3) and their typology (i.e. if direct from source to target, or conduit-mediated). Regarding investment direction, several solutions were tested, and gradient-based animations were used to graphically show which way money is moving. The types of investments are differentiated by color. Direct investments (i.e. not mediated through a conduit) were represented with green-blue gradient animations. Meanwhile,

investments indirectly mediated through conduits (including offshore investment positions) were represented with orange-fuchsia gradient animations.

3.3 Portraying uncertainty

The next task was to portray the uncertainty surrounding the value of investments (R6), which is estimated here in the absence of officially published data. For each investment, we have a "cloud" of investment size probabilities (in billions of dollars), that can be summarized in terms of statistical confidence bands. While there are a number of studies on the visualization of uncertainty (Bonneau, et al., 2014) few of them are focused on network diagrams, and in particular on uncertainty related to edges. Schwank tested several methods to portray uncertainty surrounding edge existence (Schwank, et al., 2016). The key result is that blur is a good solution to convey uncertainty. Furthermore, blur proved to be efficient in quickly enabling users to identify the most certain elements (Kosara, et al., 2002) even if not very efficient in communicating fine gradations in uncertainty level.

In the project, uncertainty is not related to the existence of a link, but rather to its weight. As out estimates take the form of statistical confidence bands, we adopted a mixed approach: the lower-bound (more certain) is drawn as an inner sharp line for each investment, while the upper-bound (less certain) estimate is drawn as a blurred outer line. The larger the blur, the larger the uncertainty (Figure 3 and Figure 4).

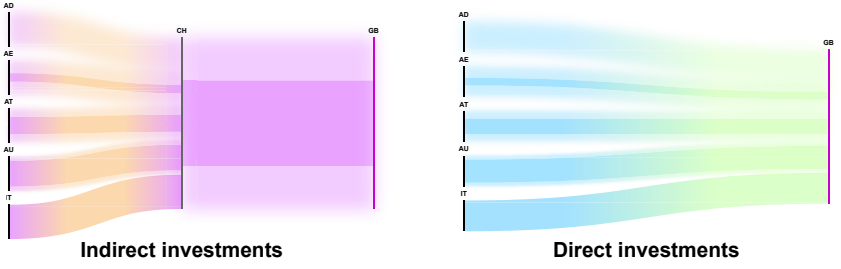

Figure 3. Example of how uncertainty level is encoded for indirect conduit (pink-organge) and direct (blue-green) investments, via blur.

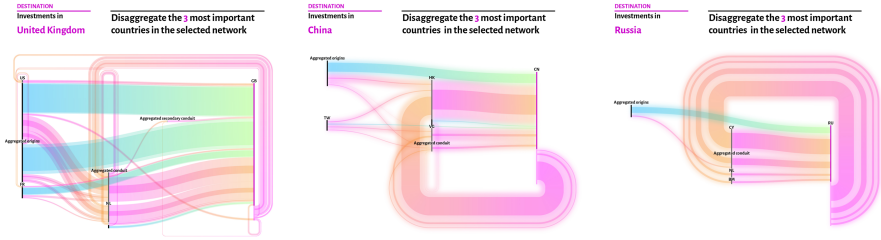

Figure 4. Visualizations of the networks of United Kingdom, China and Russia as destination countries for foreign investments, aggregated to show the 3 most important investment source and conduit countries investing in each. Note the much higher levels of blur, in general, for indirect investments passing through conduits —most of which are offshore jurisdictions— reflecting the much greater uncertainty surrounding these estimates.

3.3. Interaction design

The visual model proved to be useful in expert user tests examining a subset of data, but still too complex when attempting to show the whole database; a problem amplified by the fact that each pair of countries can be connected by several links depending on role. Furthermore, investment values fall along an enormous range, rendering the smallest ones almost invisible in the complete network. To solve these two issues, we adopted two solutions: filtering (R5) and aggregation/disaggregation (R4). The first reduces the portion of dataset visualized; the second changes its representation according to aggregation level. Both can be applied in combination.

The user can filter the investment chains displayed by selecting one (or more) countries. For example, selecting “Netherlands” will show only investment chains passing through this particular country in a role as source, conduit or target.

To reduce the visual complexity, the user can aggregate all investment chains (via a node labelled “aggregated” for each role) not involving the selected number of most important nodes in the network. At the maximum level of aggregation, only four nodes are visible: one for the target country and one for each “aggregated” jurisdiction role in the network. With a slider it is possible to progressively increase the number of individual countries that are shown in the diagram and related investments.

The interface was then enriched adding the ability to select individual nodes and links (countries and investments). Clicking on a country opens a panel showing that country’s location on the globe, as well as other key information regarding its investment pattern. Clicking on an investment it opens a panel that disaggregates all of the individual investment chains comprising it.

4. Case study / annotated lectures on the diagram

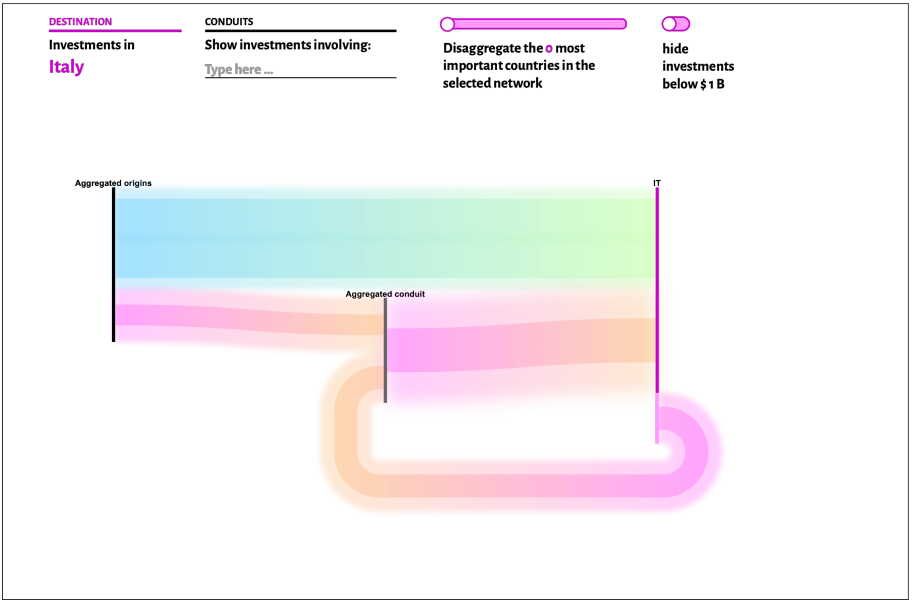

Figure 5. Network of investments targeting Italy at the maximum level of aggregation.

As an example, we can consider the network of investment targeting Italy as a destination country. At the maximum level of aggregation (Figure 5) it is possible to see that there is a single broad green-blue inflow of investment that enters Italy directly without passing through a conduit. There is also an orange-pink link entering Italy via an aggregate conduit jurisdiction — with half composed by investment ultimately originating from other countries, and half of "round-tripping" from Italy itself. From the blurriness it is also possible to see that (blue-green) direct investment that does not pass through conduits is characterized by much lower levels of estimation uncertainty than investment that enters via conduits.

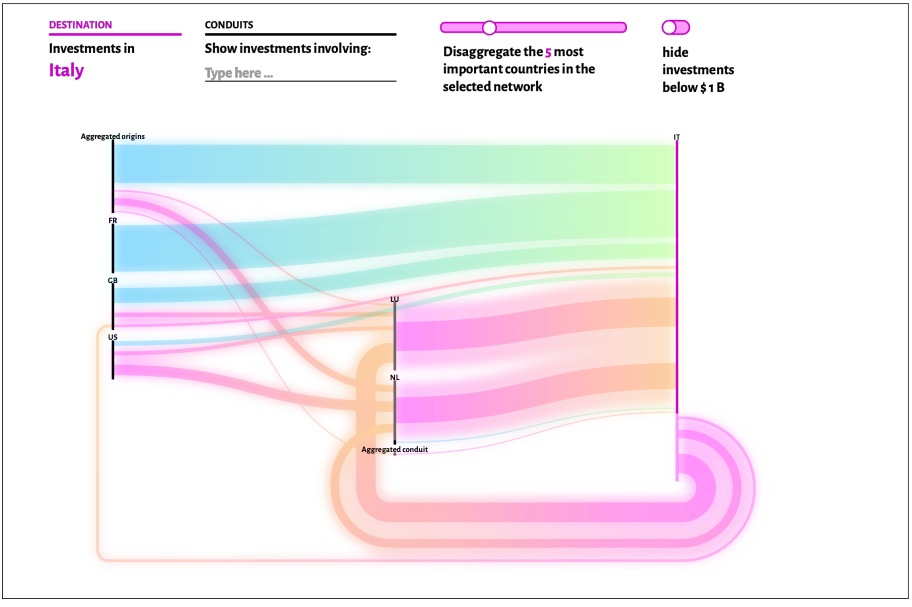

Figure 6. Network of investments targeting Italy, disaggregating the 5 most relevant countries.

By disaggregating the five most important countries (Figure 6) it is possible to see the different roles played by key source and conduit countries in the network. On the right is the target country (Italy). On the left are countries that are primary ultimate sources of investment: from France (FR) there are mainly direct ("onshore") investments, while United States (US) investment mostly enters Italy indirectly via conduit structures in the Netherlands (NL) and Luxembourg (LU). The United Kingdom (UK) plays a more complex role: it is mainly source of direct ("onshore") investment into Italy, but also both invests in Italy indirectly via conduit structures, and acts as a conduit jurisdiction itself for other countries' investments in Italy. In the middle of the diagram are the principal "conduit" countries: the Netherlands and Luxembourg. These are leading tax haven jurisdictions that both channel foreign investment into Italy, and are widely used by Italian firms and families as nodes in "round-trip" structures (i.e. where their domestic holdings in Italy are owned via offshore structures). While from the Netherlands there is also a small share of (blue-green) investment from "legitimately" Dutch companies, Luxembourg acts almost entirely as an offshore conduit, particularly for Italian round-tripping.

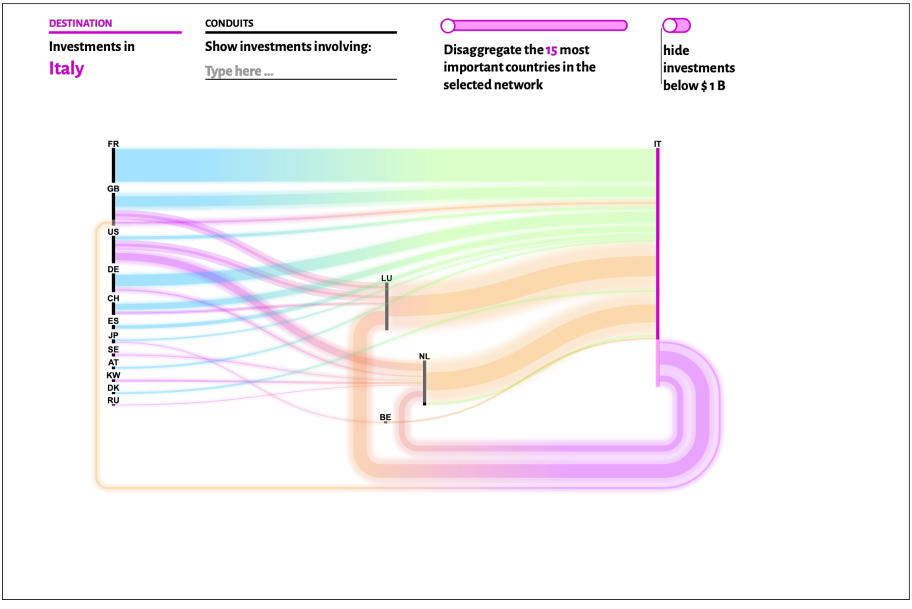

Figure 7. Network of investments targeting Italy, completely disaggregated.

Finally, by completely disaggregating the network (Figure 7) is possible to see the role of all countries providing or intermediating at least $1 billion of investment in/to Italy.

5. Conclusion / Preliminary test

In this paper we have examined the design process and decisions involved in creating the data visualization tool for an "atlas of offshore finance". We presented two design challenges surrounding the visualization of a complex multidimensional network dataset with multiple tiers of links; and the visualization of uncertainty in data based on probability estimates. After defining design requirements, a visual model and interactive strategies have been designed. The proposed solution is an interactive application based on a variant of the Sankey diagram. The application provides an overview of investments chains for a given target country; represent all the possible connections between it and layers of source and conduit countries; deals with problems of scalar differences and data overload by using filters; allowing for different flow configurations to be selectively aggregated or disaggregated; and conveying data uncertainty via the visual variable of blur.

In conclusion we offer some final reflections on what we have done and how this might point towards further work. It is important to mention that this paper focuses on the first phase of this project, namely the production of an application primarily targeted at domain

experts and initial dissemination of the results. It is also the first attempt to define a consistent visual language for the communication of such data.

While we have consulted researchers, civil society groups and other issue experts during the design process, the next phase of the project will be to enter into a public "beta testing" moment to examine broader responses to the project and to understand how this might inform further design activities.

As other researchers suggest, transparency initiatives do not only cater to pre-existing publics, they can also play a role in gathering and assembling publics (Barry, 2013; Di Salvo, 2009; Ruppert, 2015). We might thus further explore the capacities of these visualizations to gather publics and to organize material participation (Marres, 2012) in specific ways around the issue of offshore - including, e.g., relations between citizens, civil society groups, journalists, public institutions, researchers and financial industries. In future work we are particularly interested in how data visualizations may play a role beyond communicating information, including, for example, their capacities to facilitate affective engagements (Kennedy & Hill, 2018), witnessing (Gray, 2019), journalistic reporting and advocacy, the ability to create alternative narratives challenging dominant power structures (Briones Rojas, 2019).

What is particularly interesting about the case of offshore is precisely that public intelligibility is part of the issue: the numbers and estimates have been hotly contested, civil society responses have been questioned by industry, and the esoteric nature of the subject matter makes key concepts resistant to easy communication. The challenge of facilitating broader public engagement around this issue is therefore how to design visualizations which avoid misplaced precision (implying an unfounded level of certainty), whilst at the same time avoiding a kind of "data sublime" (Davies, 2015; Gray, et al., 2020) of visualizations which inadvertently reinforce the notion that offshore finance is unfathomable and publicly unintelligible. Thus, we seek to open up public debate and engagement, rather than closing it down through the affirmation of either certainty or unknowability.

Finally, the collaborative design process between researchers with different backgrounds allowed the discussion, reflection and representation of the FDI phenomenon to be conducted from multiple angles and levels. The nature of the phenomenon is not only financial, opening up issues that involve the politics of data in the construction of societies.

What does this symbol mean? Icons as a Language for Emergency

Rodrigo Ramírez[a]

Abstract | In the intersection of disciplines such as User Experience (UX) and Disaster Risk Management (DRM), this paper presents definitions from a change of paradigm: From dealing with disaster towards the management of risk, establishing the conceptual notion of Before - During - After an event. In the communication of risk, different tools are combined to deliver information about subjects, events or actions. Ideally, a well-designed message allows users to visualize, understand and facilitate decisions. However, in an emergency the experience might be radically altered. Information Design (ID) has a role to optimize messages in such disruptive contexts. In order to cope with access or language barriers, instrument devices such as icons are widely applied. Following ID principles, messages and visual tools devices need to be verified in their effectiveness. Design + Research is presented: In one hand, open-source icons representing emergencies, and in the other their international testing. Establishing performance indicators, the results reveal the importance of simple visual information tools to optimize communication. Conclusions call for an open collaboration process, focusing on a multi–disciplinary integration. Finally, observations are provided as an ongoing process.

KEYWORDS | VISUAL, INFORMATION, EMERGENCY, GLOBAL, TESTING

1. Introduction

Emergency can be considered as a complex scenario with massive demands of information. Media have revealed the impacts of natural hazards and complex transitions such as climate change. These scenarios often coincide with large disruptions such as displacements or epidemics, exacerbating their impacts. However, emergencies can also be seen as an opportunity to explore inter-cultural communication. Disruptive events have triggered cultural transformations such as information technologies and platforms or the design of public policies.

This is an important scenario to transform by design: Such a process can be constituted by individual or collective transitions that respond to the need to reduce socio-natural risks related to climate change, and in some cases, to face complex multi-hazard scenarios. In all cases, designing and delivering the right information is fundamental.

In a critical human experience such as emergency, having clear and opportune information is a key for reducing uncertainty. In order to deliver information that is visible, understandable, and simple to transfer into actions, graphic elements appear as ubiquitous tools, an immediate solution to deliver information. These tools are able to transform data into an information experience, even in critical contexts. Here, aesthetics is necessary because visual language draws on elements that are familiar, visually attractive or harmonious to users. This is also an opportunity to observe how communities construct their own interpretations.

2. Emergency as a scenario for design

International organizations such as the United Nations International Strategy for Disaster Reduction (UNISDR, 2015, 2017) define that in a disruptive human experience such as emergency, managing pertinent and opportune information is a key resource for response. Based on a model by TorqAid (2016), Figure 1 shows a conceptual diagram to show stages on the cycle of Risk Management (usually known as Disaster Risk Management, DRM).

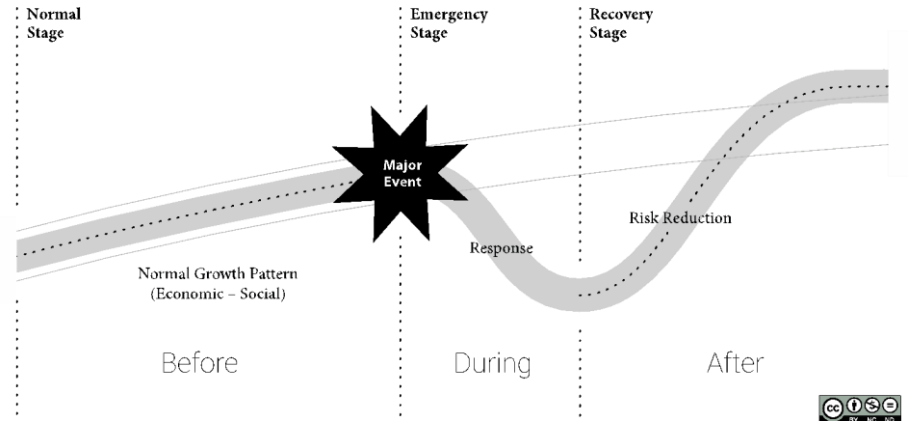

Figure 1. The Cycle of Disaster Risk Management (DRM): Stages Before - During - After. Based on the DRMC diagrammatic framework by TorqAid (2016)

Today, disciplines such as Disaster Risk Management (DRM) or Disaster Risk Reduction (DRR) are oriented to join work efforts covering different moments of cycle, promoting a multi–dimensional approach (Twigg, 2015, TorqAid, 2016). Due to human nature and its global reach, risk and emergency management emerge as one of the 'largest challenges for development' (WEF, 2017).

Concepts from the UNISDR 2015 document 'Sendai Framework for Disaster Risk Reduction 2015 – 2030' –commonly known as 'The Sendai Framework'– aims to complete risk (hazards) and emergency (disaster) as a context, consider the "organization and management of resources and responsibilities for addressing […] in particular preparedness, response and initial recovery steps". Additionally, the Sendai Framework states definitions, delivering relevant terminology to precise further discussion: i.e., Risk, Hazard, Emergency, Disaster.

Considering one from information, is fundamental to work from user needs facilitating for example to identify, learn and transfer messages into actions for a safer experience. From a human–centered focus there is an opportunity to think and apply design products and strategies to transform this scenario. As an example, the book entitled "Design for Emergency Management" (DNEM, 2019) is a comprehensive guide, a handbook on how to conduct emergency by design. Therefore, there is a transition from reducing the impact of disasters to the management of risk. Here, design is a key connector.

The International Standards Organization, ISO (2009) defines User Experience as “a person's perceptions and responses that result from the use or anticipated use of a product, system or service”. Thus, terms are extended as “user studies” or “usability”, towards disciplinary such as “prevention” or “preparedness”. This is an opportunity to increase awareness on how design can be related: Experiencing crisis is an opportunity to reshape the experience, developing simple communication tools.

A fundamental factor in an everyday experience is information, and its usual manifestation is known as Information Design (ID). Being a response to people’s need to “understand and use” large amounts of information, such discipline has been defined as the “art and science of preparing information to be used by human beings with efficiency and effectiveness” (Horn, 1999). Based on Frascara (2015) definition, ID usually draws on graphic resources such as typography, diagrams or infographics, intending to be an instrument to interact and perform with contents, constituting graphic tools that can be systematically distributed along a user experience. Figure 2 shows a sequence presented by Allard, Briones, et al (2014), a three-step virtuous cycle in ID is Seeing > Understanding > Using information.

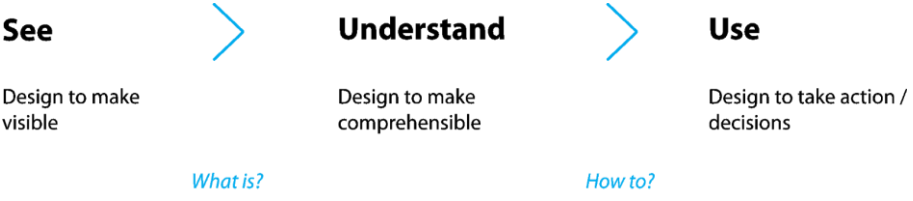

Figure 2. See > Understand > Use Information framework. Adapted from Allard, Briones et al, 2014

It is possible to transform the experience by an opportune delivered and adequately designed information, and as UNISDR (2015) states, an effective information “can avoid the escalation of an event into a disaster.” However, usually communication is less effective during a critical scenario (i.e., for reaction), thus a critical task is to observe how their components should perform.

As is stated in the UNISDR guidelines “Public Communication for Disaster Risk Reduction” by Robinson (2017), tools for effective communication such as those activated by information technologies appears to be very efficient today, and advances in technology have improved scientific risk information dramatically. Thus, some questions aims to recognize if information is visible, understandable and applicable; for example “What are factors that impede transferring information into action?; why action is ignored during an emergency?”

In a world usually plenty of information, a key to integrate UX and DRM might be identifying contents, typologies, moments and originators of information in a common way, making

visible for example: Who (i.e., responsible - originator), What (i.e., actions - options), or How (i.e., procedures).

Mixing multi-disciplinary approaches, new considerations emerge: Figure 2 shows a sequence, considering information design as a continuum to support human experience, starting from identifying hazards or understanding vulnerability, to action and reaction in a disruptive situation, towards a relief, assembly or procedures for recovery, in a continuum articulated by information.

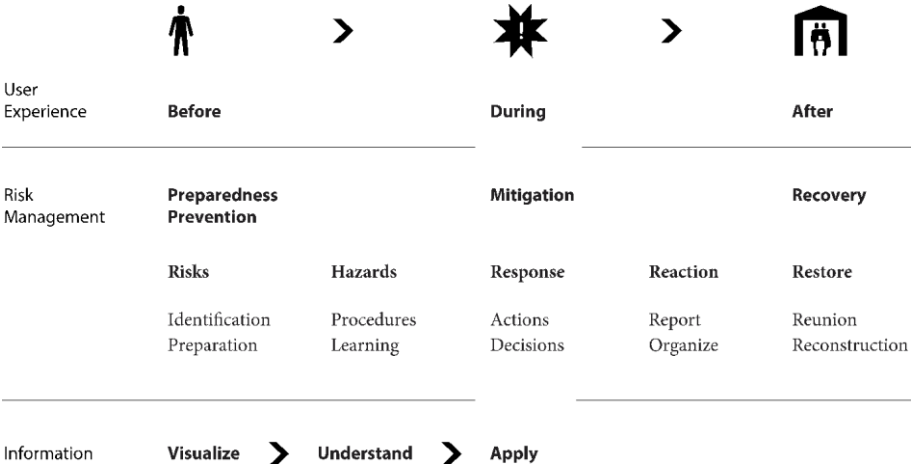

Figure 3. Figure 3. UX + DRM + Information, with focus on communication actions.

As figure 3 conceptualizes, a clear language can decisively contribute to articulate information needs in a critical context, making visible and transforming an uncertain experience into an understandable one. Here for example, information might be applied to identify, create awareness, or facilitate preparedness. During an emergency, information is a key to respond or take decisions. It may help to identify and learn from already known hazards, contributing to reducing their effects. After a critical event, information becomes necessary because such disruptive scenarios usually imply limited access to communication, probably one of the most difficult challenges for recovery. Therefore, a big challenge is how to integrate different supports in all emergency stages to conduct an experience driven by information. Considering moments such as Before - During - After an event, it is fundamental to consider a pertinent, clear language to deliver information.

3. A language for emergency

In everyday life, visual Language have multiple approaches, visual tools such as symbols or icons constitute a simple, global 'lingua franca' to create an expressive language and performance of information. Commonly called symbols, pictograms or icons, these are normalized images designed to display concrete meanings (Jardí, 2011). In everyday life, icons are a codified language integrated with communication systems displaying consistent information on multiple supports. However, presenting information that leads to action might represent a cognitive challenge for users in critical scenarios such as in an emergency. As Boersema & Adams (2017) state, different standards of symbols have been developed for diverse contexts such as transport, public spaces or safety at work, always aiming to reach "universal" interpretation.

An emergency can be defined as "a disruptive situation that transforms the expected course of an event. Here, both personal and collective relationships become affected, altering what is considered a normal experience". Due to human nature and its global reach, risk and emergency management emerge as one of "largest challenges for development" (WEF, 2017).

However, due to their technical complexity or dependence of technology, data might constitute a poor information experience. Being a complex scenario with large information needs, emergency emerges as a challenging context for the design of systems. From an Information Design perspective, this paper is oriented to present definitions and practice, crossing both user experience and cycle of risk disciplines. In this intersection, visual elements such as icons constitute a visual tool oriented to support critical scenarios by information. In specific context of emergency, different initiatives are developed considering context (i.e. a crisis) or specific actions (i.e. evacuate).

However, what about the contextual constraints in human experience? This paper is oriented to develop visual research as a method of inquiry and delivering results on performance of icons as visual language for emergency. Specifically, the application and evaluation of icons as units of meaning for global communication, preparedness and the education of risk.

Such critical context suggests that icons need to be verified in their effectiveness. An indicator to verify language performance is testing. As a literature review shows (Brugger, 1999, Frascara, 2001 ISO, 2007), a fundamental index to evaluate icons is Comprehension. This is an opportunity to explore a language and evaluate their interpretations for emergency.

An open source icon initiative to represent risk and emergency situations is presented. This is an emergent case study including the set of icons, an international testing initiative to evaluate symbols, and activities to creatively work on emergency with communities. Beyond

the design process, this case opens challenging questions about the importance of consistent visual language for disruptive scenarios.

4. An opportunity for a “Language for Emergency”

As mentioned, emergency is a complex experience usually with large demands of information. On the other hand, visual tools such as icons emerge as optimal instruments to handle multiple communication challenges (i.e. accessibility, language, technology).

As a *lingua franca* of the information age, icon systems should be able to present and understand precise meanings implemented by punctual visual elements. Articulated as part of a system, these simple graphic components can play a fundamental role delivering information for multiple moments or decisions. Therefore, a consistent visual language practice can decisively contribute to manage emergency, from identification and preparation –Before–, to reaction –During– towards active recovery –After–.

Here, Guemil is considered as a study case. Their design concept is to represent information for different stages of the cycle of risk (before – during – after an emergency).This is an open source initiative to represent risk and emergency, making available a visual tool for information, but also might activate new conversations on how to optimize preparation and contribute to community resilience applying simple, consistent resources to enhance communication, this is called a “Language for Emergency.” Moreover, the case from these icons constitutes an applied design + research project with multiple outcomes such as collaborative design and workshops. Figure 4 shows the current icon set.

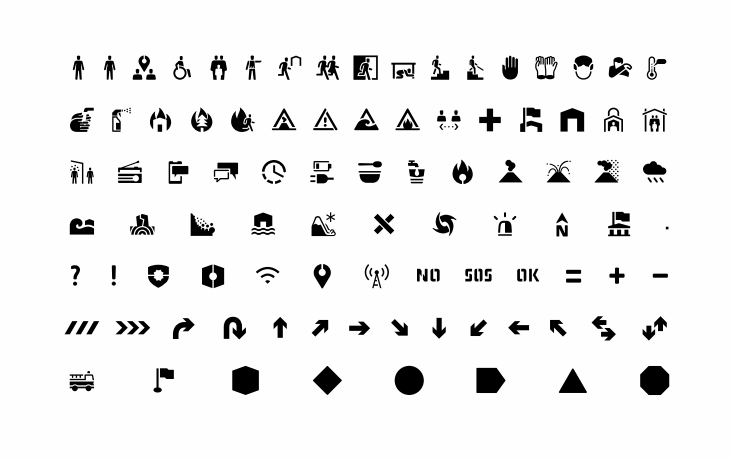

Figure 4: Guemil Icons set (v15, 2020)

5. What does mean this icon?

In communication for disaster, as Kremer (2016) remarks, providing “unambiguous iconography can make a difference […]” However, after visual design stage the implementation of public symbols is usually assumed as is. For the International Institute for Information Design (IIID), one core competency is “Initiate the testing of use and usability, evaluate the test results and refine the information accordingly.” (idX, 2007). Thereby, graphic elements such as symbols and typography appear as ubiquitous solutions delivering visible and legible information to articulate action.

In the other hand, considering only a conceptual or styling statement from originators seems not to be enough: Through a combination of perception and reasoning, evidence about communicative performance is fundamental to demonstrate their effectiveness. Oriented to perform certainly in critical situations, previously users need to visualize and learn what specific information is being represented. In other words, if visual systems are oriented to operate in critical contexts such as emergency, an evidence of performance might be provided. Therefore, performance tests were designed to complement the design of icons, complementing their visual design with interpretation indicators. In the process, data from tests was collected and divided by country, age range or education level. Figure 5 shows the initial concept, constituting a simple base to collect, observe or to compare recognition patterns.

Figure 5. The question from testing forms, in Chinese

In this case visual tools should provide cognitive evidence about what is understood (loose or precise meaning), and what is potentially generating multiple interpretations (or confusion) in emergency contexts.

6. Insights from global tests

After the visual design phase, since 2016 an international testing process is ongoing, showing different icons and asking users about two indicators: Meaning and Differences. A large dataset is generated, and a selection of results is presented for discussion.

According to international practice, evidence of performance as an index is constructed mainly by asking users about Comprehension (Brugger 1999; Olygay, 2003; Frascara 2011; ISO 2011). Thus, in the "Meaning" test responses were collected from an open interpretation of each icon. Here, the single question was "What does this icon mean?" presenting an image to be interpreted by the tester. Then, such an answer is matched with its denomination, categorizing the response according to a 6-grade scale. Therefore, beyond the visual design problem, analyzing responses collected from evaluations might reveal new relations from users' interpretations. Figure 6 shows the project's website, illustrating a performance index for each icon.

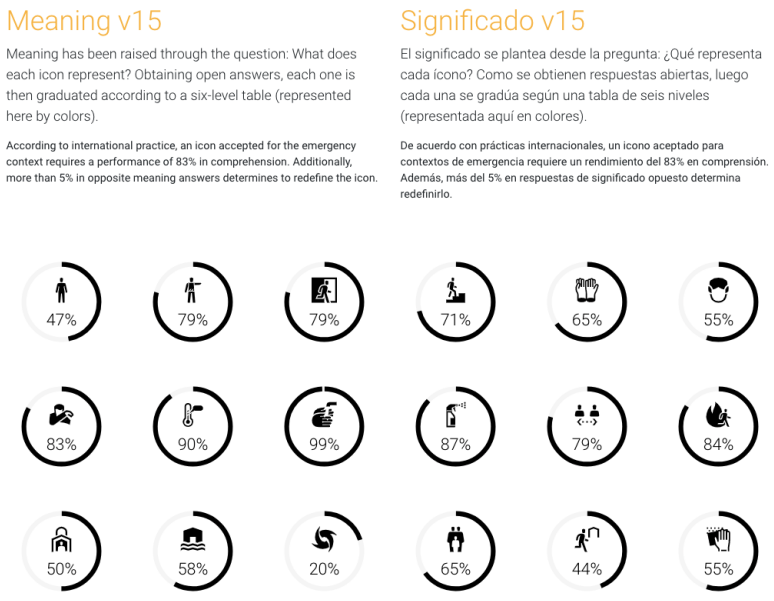

Figure 6. Guemil website, visualizing the meaning tests results, 2020. Source: test.guemil.info

In the second test, "Preferences" were collected from identifying characteristics associated to a concept among different icons, recognizing particular elements. Here, the single question was "Which of these icons does represent…?" Thereby, according to the

categorization of usability testing by Chisnell & Rubin (2008) this test might be considered as an Exploratory evaluation, where users were asked to select from a series of representations, which of those “matched” a defined concept or message.

Visualizations of results give shape to ideas about interpretation of the emergency. After this preliminary process with results being analyzed, such experience was considered to improve icons, presenting an iterated version. Also, this was an opportunity to improve the instrument. Performance validation is a way to deliver required indicators of effectiveness, but also reveals further insights connected to variables such as location, age or language. Figure 7 visualizes response patterns from the meaning tests in 2019-2020.

Practical applications

1. **Education:** As mentioned, a well–designed information should enhance preparedness, may contribute to decision making and support resilience. Topics such as design for resilience, or design for transitions can be stimulated from such initiatives. Exploring risk and emergency as an education topic is also an interesting approach to work collaboratively combining local and global impacts.

2. **Multi–cultural dialog:** A new practical significance managing such “language for Emergency”, through an inter-cultural approach to work collaboratively on disruptive scenarios. Graphic elements with common interpretation can contribute to construct meanings, then transforming a visual language into action, promoting identification of risks, preparedness, adaptation, among other factors. See Frommberger & Waidyanatha (2017).

3. **Creativity:** This is important because there is a need to raise new ways to approach crisis or emergency management. Open–access is a creative contribution to share meanings and facilitating learning by visual tools. Experiences such as by Japanese models of education suggests that resilience can be nurtured by creativity, using simple and engaging creative methods.

4. **Measuring communication:** A participative approach, collecting performance evidence is a way to measure if graphic language is effective conducting comprehensible and usable communication. This is an opportunity to explore creative and analytical approaches, balancing design thinking and doing.

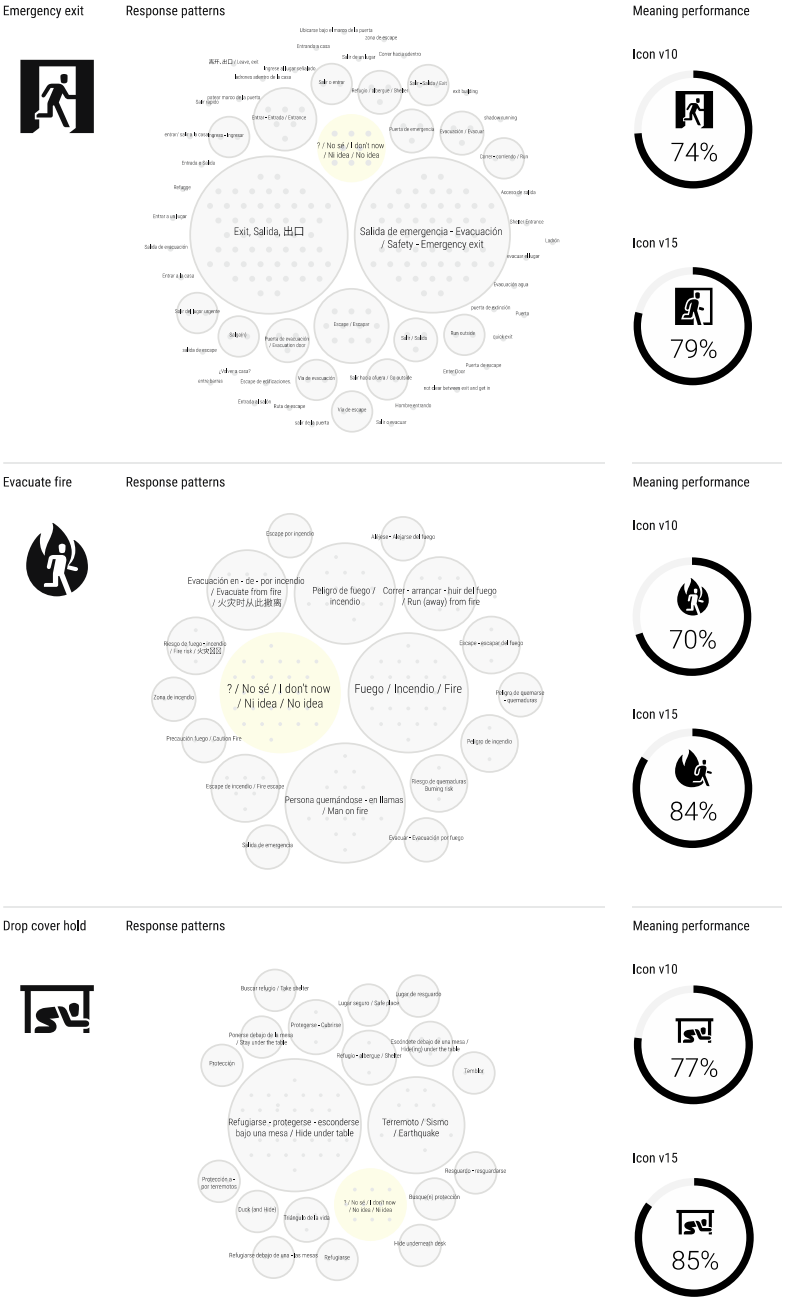

Figure 7. Test results: Icons, Response patterns and Meaning performance 2019-2020

7. Conclusion

Information Design has a relevant role –and a challenge– for visualizing, understanding and applying engaging, manageable messages in critical contexts. In other words, in a disruptive experience dealing with clear and opportune information can constitute a differentiator for the user's certainty. Guemil makes available a simple design system to visualize information for users along their experience of risk. Fundamentally, such a project constitutes an experimental research platform to explore the role of information design instruments, and to evidence how users interact with such visual language for emergencies.

Critical scenarios are posing new ways to collaborate, experiment and interact with information. In the process, tools and methods by design have been developed. Collaborative initiatives designed for “new normal” contexts and based on visual language, seems to prevail to communicate globally.

Research is a key to evidence performance, tests responses demonstrate challenging insights to share, making necessary to continue analyzing the results in a project will be iterating continuously. Figure 8 shows the responses on Differences Tests from 20 countries during 2018.

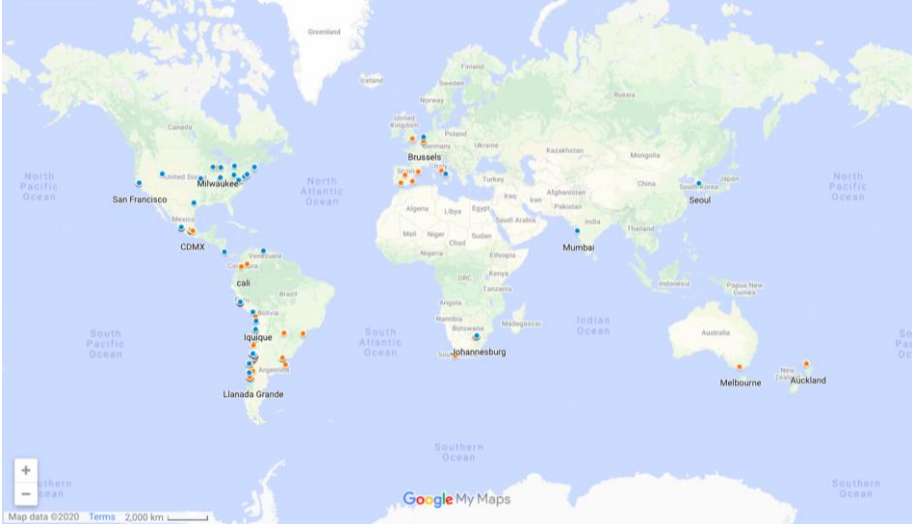

Figure 8. A map showing global responses from testing (2020). Source: Google Maps

Finally, considering that results so far are part of an ongoing process, reflections are presented to generate discussion and stimulate further collaboration:

1. Graphic language can be considered as a key resource to activate meaningful communication and promote action. ID contributes to optimize the experience of emergency, articulating information as a continuum.

However, as a research + development process this has been an opportunity to compare local–global perceptions and interpretations, Moreover, such international process allows to recognize local interpretation on icons, risks and emergency scenarios, generating relevant performance evidence and questioning their notion of “universal language”.

2. Upcoming scenarios such as climate change, migrations or adaptive education demand urgently to continue global initiatives based on common grounds such as visual language and the design of information. Open initiatives and interaction design can facilitate dialogs adding new dimensions to project–based research work. They require new ways to engage and experience the emergency, creating resilience, this is an open invitation to collaborate.

3. An interdisciplinary approach is fundamental to explore wicked challenges. Therefore, promoting such projects might contribute to their adoption and stimulate global connections, with a bottom-up approach, relying on collaboration. This might help to generate common interpretations on information for emergency, for example for preparedness and reaction.

4. Multi-cultural communication is an opportunity to open dialog. Actions are oriented to generate discussion on the role of graphic tools for emergency, from local initiatives to international communication platforms, emphasizing the role of information design as a practical, global scale activator for the experience of emergency, as figure 9 illustrates.

Figure 9. The workshop: Visual Information for Emergency, is an icon-driven, hands-on experience to dialog and create about the role of information in emergency scenarios. Image from the 2019 Design for Transitions International Conferences at Jiangnan University, Wuxi China.

As an ongoing project, results also challenge prevalent notions such as "Universal" language traditionally prejudged for icons, exploring local interpretations as knowledge. However, results and connections are going to be presented and open to discuss from multiple perspectives. Beyond just designing a "Language for Emergency", such research shows cultural implications, suggesting the need of strategies for larger-scale transformation processes in the public realm, such as creative, adaptive education or resilience.

Abstract | Based on two study cases of product design students' projects this paper analyses how both theoretical and practical research can inform design methods' development leading to the creation of new form language and expansion of design aesthetics beyond the functionalist paradigm. This paper outlines methodological approaches to integrate design research in practice-based projects to develop new form languages. Transmitting the conceptual and discursive implications of the employed design method is, in particular, challenging within undergraduate design education, that is often depoliticised and service-oriented (Decolonising Design, 2018). Defining the choice of methods as always a political one, the authors of this paper focus on the research as a self-reflecting process that draws from the notion of "designing design" – i.e. on the notion of an open, developing methodology always under scrutiny through practice (Schön, 2017).

KEYWORDS | DESIGN EDUCATION, DESIGN THEORY, DESIGN METHODOLOGY, DESIGN CULTURE

1. Introduction

First two decades of the 21st century have witnessed the establishment of design culture as a scholarly discipline (Buchanan Margolin, 1995; Julier, 2006), which laid ground for a contextualised, theory-informed design education, contributing to the development of new design languages and a broader understanding of design culture. In this paper, we define Design Culture on different levels: as a process of carrying out design, as a context-informed practice within its societal, cultural, geographical milieu, as an agency for a transformative design action (Julier, 2006, pp. 70-72). Within this framework, we propose to understand Design Culture, not as one homogenous entity, rather as “a world where many worlds fit” (Escobar 2018; Abdulla, 2018). We believe that to foster this pluriversal instead of the universal understanding of design; we must move beyond the functionalist, service-oriented paradigm of the discipline towards critical, research-informed design practice (Abdulla, 2018). These design practices acknowledge new modes of *doing* design. In this process, theory and practice are mutually supportive, and designers – following educational theorist Donald Schön – exercise reflexivity “on action” and “in action” during and following their work. (Schön, 2017; Cal Swann, 2002). Going towards these situated practices, we have to foster design education that is student-centered and enables students to discover what is relevant for their future practice. So, we see education as future building, and the methods – developed in this process of future building – are fluid rather than constant, continuously changing and adapting, responding to the context.

In this paper, we discuss two study-cases of projects developed by industrial design undergraduate students as part of their final project and the methods they developed within the design process. Based on these two cases, this paper explores methodological approaches that can contribute to the broader integration of design research in practice-based-projects and as consequence creation of new form languages, new aesthetics, new visual worlds.

2. Context: Undergraduate Design Education at Universities of Applied Sciences in Switzerland

Following the recommendations of the Bologna Declaration, the two-cycle degree structure of design education puts pressure on delivering skills and methodological knowledge to undergraduate students. In Switzerland, Bologna reform ended the period of vocational education at traditional arts and crafts schools, which had sprung up all over Europe in the latter third of the 19th century (Ernst, 2014, p. 358). Seven Universities of Applied Sciences offer courses in design. The commotion surrounding so-called "academisation" of design belied the fact that the reform in design training led to a real wave of development, and to redefining educational practices.

The following two cases are an attempt to apply a student-centred pedagogical approach in undergraduate industrial design studies. Similar to research-based-learning methods, students develop an investigative attitude in addition to the development of necessary skills, i.e. formulating their own hypotheses and iteratively testing them in form of prototypes.

During the short three years leading up to a Bachelors' degree, students learn at least once how they have to play an active part in defining their aims and methods of a design process. The BA degree project consists of two equally weighted parts: a practical and a theoretical thesis. Referring to two study cases, we will discuss in this paper how the approaches mentioned above interact beyond, project-related enquiry and lead students to define their design methods for their future practice. It is not the aim of this paper to offer universal educational solutions, as we believe that those have proven to be ineffective, instead to focus on the situatedness uniqueness of the presented cases (Stake, 2015, p.6)

3. Case #01: Non-visual input and creation of a conceptual framework to address aesthetics in design

The first case examines a strikingly simple, but fundamental question (Halmes, 2019): How and to what extent do the sighted and the blind or severely visually impaired differ in their perception of objects' beauty? Within her project, Alena Halmes explores how people who are visually impaired understand beauty and how their perception of sounds and fluid can guide the creation of a new form language in product design. Her project is twofold; the first part is theoretical research; the second is a practice-based project informed by this qualitative study. She situates the research within a predominantly ocular-centric western world of thought, which values epistemologies based on visual or ocular metaphors. Already the Greek philosophers recognised sight as the most powerful sense; since the 18th-century European philosophers have extensively described the hermeneutical power of vision (Levin, 1997). Despite the critique on the prevalence of vision in epistemology in 20th-century philosophy, design is still heavily influenced by such metaphors. Terms like form language or semantics design are understood mainly visually, reducing aesthetic criteria in an object-related design to solely visual ones. Colours and shapes constitute prevalent aesthetic criteria in objects' description, at the same time, both design criticism and education neglect haptic and olfactory aspects of artefacts.

Halmes refers to several studies that have shown the specificity of perceiving the world by people who are blind and visually impaired as they excel in recognising shapes. They are also more accurate in detecting textures, and they estimate distances in steps better because they depend on this ability in their daily life. (Halmes, 2019, p. 1) Based on this knowledge, Halmes asks: How can we talk about beauty, itself a challenging endeavour, if we experience the world based on different epistemologies? Conducting her study, Halmes tried to gain a reflective understanding of the experience of being blind or visually impaired. At the same

time, she explored related topics such as silence and noise, or day and night. These observations would further guide her in the design process.

Methodologically, she conceived a field study that implied six participants: three sighted, two partially sighted and one person who was blind, asking them to bring three objects they consider beautiful, as the prop to begin a conversation on beauty. To limit the criteria of choice, she asked the interlocutors to bring with them objects related to kitchen, leisure, or work. In the semi-structured interview, the author asked the participants the following questions:

1. Do you find any part of the object particularly beautiful?
2. Is the function more important than the material and formal properties of the object?
3. Would your perception change if you could not see the object (for the sighted) or if they could see it (for the visually impaired)?

Following the interview, she presented a series of objects to the participants (a folding chair, salad servers and a folder, asking about the aesthetic quality of each of them). At the end of each interview, the participants had to answer spontaneously, how they defined beauty for themselves. From this conversation, she extracted beauty criteria that she discussed in detail with the participants scrutinising the use of the word “beautiful” as well as the language used by the participants. Asked about their understanding of beauty, they mentioned mainly haptic criteria as they spoke of warm and subtle surfaces, of round and soft shapes, of the organic, of nature. It led them to be specifically attentive to auditive criteria – to the sound objects make. Using a spider’s web diagram, the author compared the weighted criteria of sighted and visually impaired participants.

She concluded that despite the highly individual interpretation of functional and visually, auditive, haptic, production- and memory-related criteria by all her participants, there is a predominance of haptic interaction of people who are blind and visually impaired, grounding their notion of beauty. The author could prove further that the blind and the two severely visually impaired participants are fragmenting the experience of objects and therefore perceive them in more detail allowing them to formulate more precise judgements about haptic quality and materialisation of the objects. The constant flow of haptic perception and the importance of sound as the base of aesthetic experience described by the participants who are blind and visually impaired became the starting points of the design process. Halmes focused on glass as a specifically interesting material in this context: It is transparent, its specific haptic quality connects it with liquids, and it sounds beautifully.

The process of qualitative research does not attempt to generate a theory, instead lays ground for product development, in which the question of how we can use non-visual inputs as guidelines for developing a new form language. Exploring objects is a haptic and sonic experience, therefore using these two inputs opens up new possibilities for design. Trying to explore the sonic potential of objects, Alena Halmes started to examine the history and

typology of wine glasses. In parallel, she deformed existing glasses and investigated how the tone changed in the process. This hands-on research was both history-informed (history of different shapes and glass production modes) as well driven by the findings from the interviews. Interviewing the people who are blind, Halmes accessed “hidden knowledge” (Haraway, 1988) and learned how they interact with objects, touching them from the bottom to the top, trying to avoid “fishing around in the air”. Based on this knowledge, she sketched sounds and shapes from bottom to top.

Flipping through her sketchbook, one discovers hundreds of glasses; distorted, oblique, or fluted. The glass that represents the sound of a singer has ribbed edges; another glass resembles a column as a way of imagining the sound of an engine. (Schmid, 2019, p. 54) Drawing was a crucial and liberating part of the process, in which she broke away from a conventional theory of forms based on visual experience. At this point in the process Halmes was trying to mimic the perception of sound by the blind people and interpret it her way. Informing her project with political theory and criticism of traditional participatory design methods that take the agency of the participants was a significant turning point for the project. This shows how important it is to create curricula that encourage critical thinking and create spaces “where students can engage critically with their experiences, surroundings and reality” (Abdulla, 2018, p. 292).

Figure 1. Trying to explore the sonic potential of objects, Alena Halmes started to examine the history and typology of wine glasses. In parallel, she deformed existing glasses and investigated how the tone changed in the process.

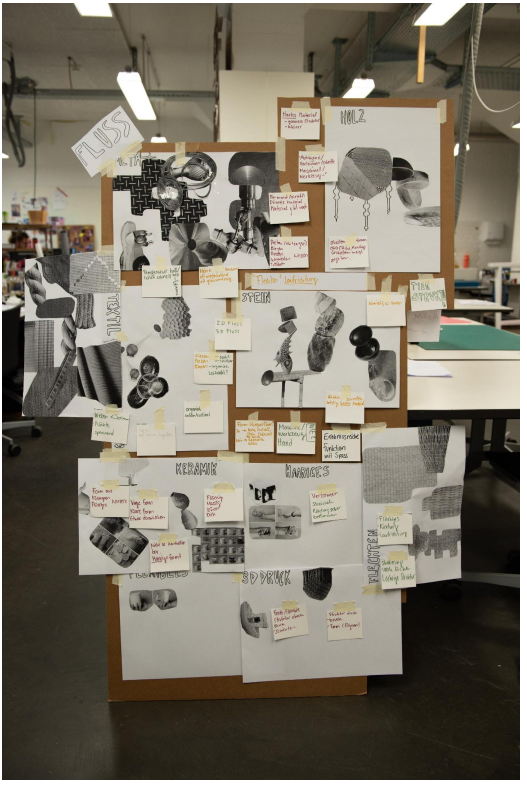

Figure 2. Alena Halmes used a pin board to keep sketches and found material available in the design process. This helped her not only to make decisions, but to argue them with mentors and to reflect the process.

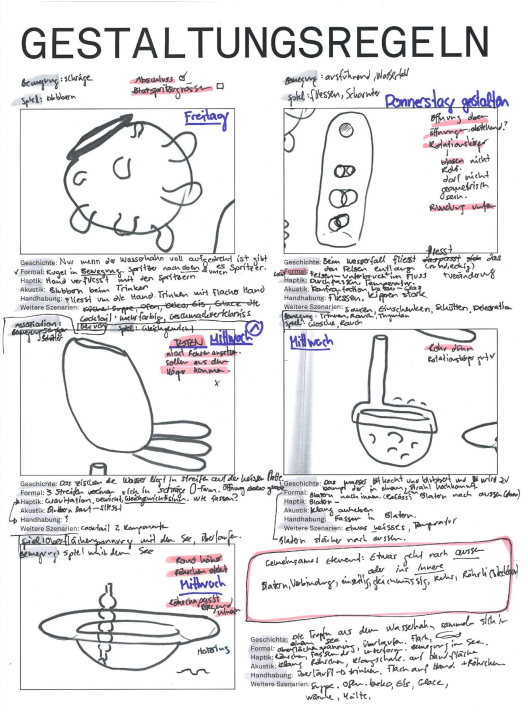

Figure 3. From the descriptions, the most distinctive features were distilled. Translated to sketches and cardboard models of the glasses, Halmes was able to check her interpretation with the blind person and define the form of the final cocktail glass collection.

Halmes finally realised that she wanted to leave the translation of sounds into glass to the people who are blind. She got in contact with two women blind from birth with whom she intensively talked about their notion of water noises – the bubbling, swirling, hissing, and dripping of water in a whirlpool, on a boiling plate, or from a tap. How can a blind person imagine the visual analogy? From the descriptions, she distilled the most distinctive features. Translated to cardboard models of the glasses in a first design round, Halmes was able to check her interpretation with the blind person and define the form of the final cocktail glass collection. She could anticipate some of the sounds of the glasses translating the sonic experience of these interviewees. Collecting qualitative data and translating them into detailed drawings was necessary to collaborate with a glassblower, who produced the glasses.

Figure 4. The form of the final cocktail glass collection.

This way a collection of cocktail glasses was created, breaking with the standard form language that praises functionality, instead an entirely new form language emerges from the perceptions of the blind people. Through the glasses, we can partake in a world of experience otherwise inaccessible. However, there is more to this project. In the process, the long-disputed binary of objects having either strictly functional or symbolic qualities is dissolved (Findeli, 1994). Using semi-structured interviews as part of her qualitative research led the design process. Through a constant dialogue which implies that the knowledge is co-created between the researcher and the researched (Nagy Hesse-Biber & Leavy, 2011) a series of glasses was created, that translates haptic and acoustic perceptions into three-dimensional forms. During the design process, the student used reflexivity to overcome her bias as a sighted person, understanding blindness as a chance to integrate the non-visual into the design. The result is a design that moves away from the purely functional and towards the integration of the aesthetics of the non-visual into the design. The student was able to overcome traditional design methodologies and found her method of exploring different possibilities of perception. Trained to listen and look carefully, she developed an approach that is fundamental for any design process. Ultimately, the project shows how research can inform methodology that celebrates diverse forms of perception.

4. Case #02: Historical research as a design tool

The second case highlights how using design history as a starting point for a design process leads to new approaches towards existing typologies and form language. At the same time, it criticises the notion of national design production and canon building. Exploring three historical debates, Elias Kopp updated and used them as a base and guideline for three chair concepts. (Kopp, 2019) This case shows how discursive and historiographical methods can be meaningful within the design process, expanding general knowledge of temporal social, and practical circumstances. The resulting prototypes show the competence to classify, criticise and continue inscribing this knowledge into new forms. In looking back, the student thought of "how to project forward", creating something that would have "otherwise not be considered" (Fry, 2008, p. 39) This approach also fosters design education that is history-informed, rather than dehistoricised as is often the case within many programmes (Fry, et al., 2015) As such and on the level of design education, the project makes a point of what Noel Waite defines as the overall purpose of design history in educating

> "critical, creative and reflective design practitioners, as well as to sustain research-informed design practice within an interdisciplinary Design Studies undergraduate programme." (Waite, 2016)

Methodologically, the author proceeds from an analysis of past debates, which he consistently summarises. He is particularly convincing in his independent interpretation of the debates in terms of their topicality for contemporary design work and in deriving his design methodology out of this analysis. Instead of discerning formal qualities of designed objects of Swiss origin and ascribing them a kind of «national characteristics» (which would have led him into a sort of circular reasoning), he examines three distinct debates of the 20th century. They centre on production, morality and emotion, headed as "typification", "good form" and "postmodern critique of functionalism". In his concise and consistent discussion of these past debates, he draws primarily on the still scarce literature on Swiss industrial design (cf. Schilder Bär & Wild, 2001; Brändle, et al., 2015). Each of these summarising chapters is followed by a reflection in which the author questions the discourses about their topicality. As the most significant contribution of the thesis, they support the design process and the decisions the author had to take in conceiving three chairs.

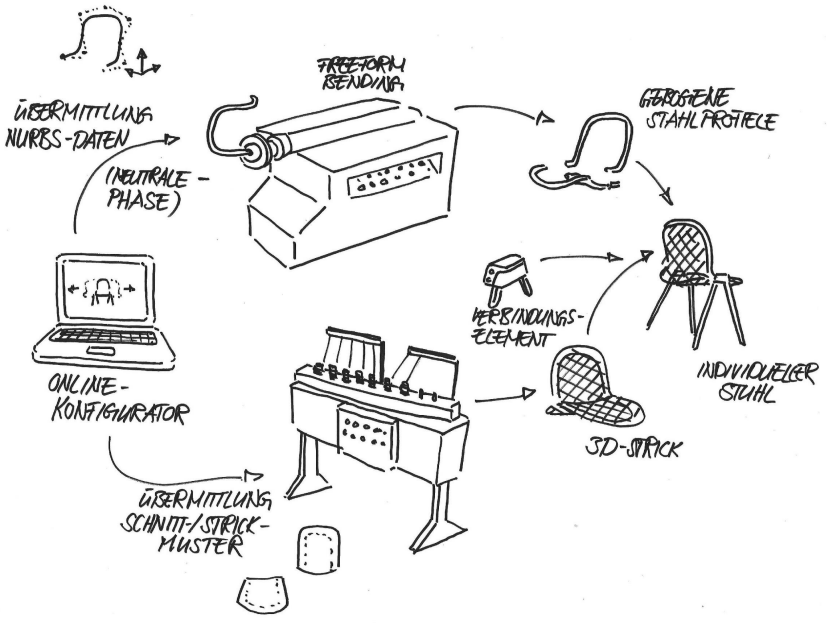

Figure 5. Today's digital production such as CNC, plotters or laser cutters enables a close interlocking of the design process, industrial production and the market. It relates historically to the struggle of typification in the early 20th century.

The first chapter, entitled "Form follows Production", is dedicated to typification, which historically links to the industrial revolution and which led to the development of the professional industrial design. In comparison to mass production at the beginning of the 20th century, today's digital production methods such as CNC, plotters or laser cutters enable a close interlocking of the design process, industrial production and the market. Thus, typification no longer has to be aimed at the conception of entire objects for easy industrialisation. Instead, it focuses on core elements which (as in the case of the chair) can be conceived as connections or complex load-bearing components defining the chair as systems design. Such arguing helps the author to liberate himself from an object-related design approach especially prevalent in chair design as the cornerstone and a cliché of design history.

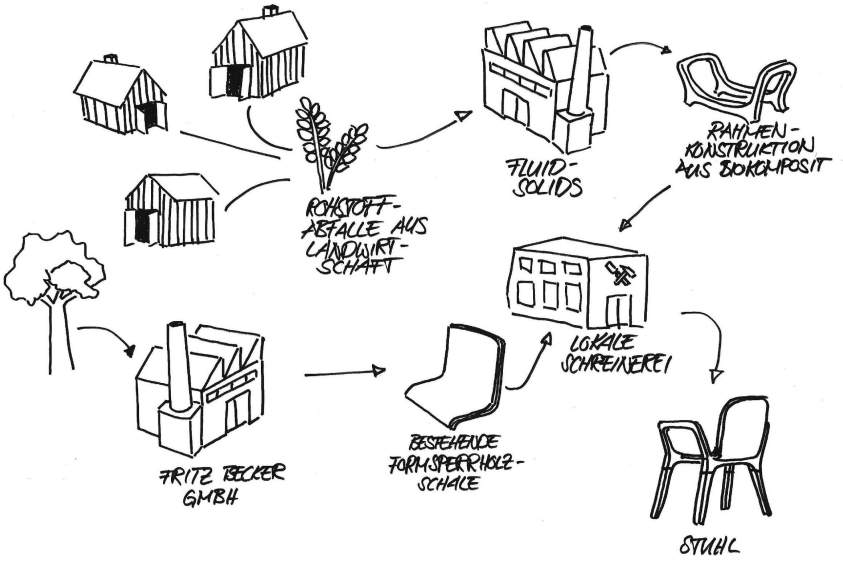

Figure 6. With «Form follows morality» the author discusses a topical debate that mirrors the historical development from design-related ideology of «good form» and the discussion of sustainability in the early seventies to the notion of a new formgiving factor of the system.

The author then updates the debate on "good form" from around 1950 under the title "Form follows morality". With a view to Burckhardt (1980), he concludes that not only an object but an entire, often opaque system must be designed "well", whereby questions of (ecological) sustainability have now joined and even overcome the intricate interaction of functional and aesthetic factors (Bill, 1949).

The third debate under the title "Form follows emotion" refers to emphasizing the symbolic function of design in the 1980s. It formulated a much-needed critique of rationalism even more growing since the late 1960s, that led to the semantic turn (Krippendorf, 2006). In its wake, it also propagated an authorial design approach primarily concerned with formal aesthetics. However, as the author points out, this attitude did not criticise consumer behaviour but, on the contrary, propagated it. Ultimately, this resulted in maintaining the economic system of fast-changing styles and fashions, mediated through the upcoming internet in the mid-nineties. Reacting to this, the author proposes instead to dissolve the product as a container of formal aesthetic meaning and thus to reformulate the industrial production apparatus. Through adapting and refreshing existing DIY concepts, utilizing Fablabs and conceiving small series, he criticizes the traditional market.

Figure 7. With «Form follows emotion» the author adapts and refreshes existing DIY concepts, utilising Fablabs and conceiving small series to overcome authorial approaches and to democratize design.

In a concluding chapter, the author summarizes his observations. Since he was not concerned with defining and debating formal aesthetics, but with the analysis of values that guide design processes, the answer to the question of whether there are specific local or national characteristics, a "CH – Design – DNA", is correspondingly general. The author mentions the "ideological focus on quality and function" and the fact that most designers in Switzerland historically took a mediating rather than an avant-garde position in design-related debates. However, he assigns a high degree of urgency to the three aspects of production, morality and emotion derived from the historical debates for past and current design work, thus acquiring a guideline for his future practice. Consequently, this enables him to knowingly and critically align himself in a specific design tradition.

A more comprehensive justification for the selection of the three debates classified as necessary would have been helpful – here; the student reaches the limits of historiographical expertise that go beyond the requirements for a Bachelor's thesis in design. Nevertheless, in a close reading of a few seminal historical debates, he not only comes to clarifications that are essential for any design practice. Together with the practical thesis, it is thus evident what an important role the confrontation with the history of one's discipline

can play for design. The student was able to develop a founded personal standpoint as a designer aiming at rewriting history through design. This is also evident in the practical thesis, which not only benefits from the examination of past debates and decisions but also updates it in the form of design-related solutions at prototype level. Thus, he creates a close link between theory and practice that is mutually supportive.

5. Conclusions

Both cases show from a different angle, the value of theory- and research-informed design practice. They postulate for design education that encourages these ways of *doing* design, where the impulse of making is accompanied by thorough research. Consequently, as teachers, we should encourage students to find their own ways in combining research methods borrowed from social sciences, critical studies and design history to enrich their practice adding a new layer of knowledge.

The first case exemplifies the importance of qualitative research within the design process. Through the outcome, the glasses, we can partake in a world of experience otherwise inaccessible. This study case shows how Halmes, instead of appropriating and mimicking the ways how blind people experience sound, shape, fluids, therefore creating the representation of the representation, and taking over the agency, made space in the project for the voices of the people with whom she collaborated. Therefore, she decided to conduct a series of semi-structured interviews with three people who were blind from birth and asked them a set of questions. This way she instead of creating a general, universal theory, she focused on the particular uniqueness of each one's perception, so the translation of sounds into three-dimensional forms would be guided by their understanding. She asked the following questions: How do they conceive the images and movements of water sounds? How can they imagine something that, like water, is so elusive and therefore impossible to touch?

But there is more to this project. In the process, the long-disputed binary of objects having either strictly functional or symbolic qualities is dissolved (Findeli, 1994). Using semi-structured interviews as part of her qualitative research led the design process. Through a constant dialogue which implies that the knowledge is co-created between the researcher and the researched (Nagy Hesse-Biber & Leavy, 2011) a series of glasses was created, that translates haptic and acoustic perceptions into three-dimensional forms. During the design process, the student used reflexivity to overcome her bias as a sighted person, understanding blindness as a chance to integrate the non-visual into the design. The result is a design that moves away from the purely functional and towards the integration of the aesthetics of the non-visual into the design. The student was able to overcome traditional design methodologies and found her own method, exploring different possibilities of perception. Trained to listen and look carefully, she developed an approach that is

fundamental for any design process. Finally, this project shows that every perception is individual and of equal value.

The second case shows how to close the often-lamented gap between theory and practice, design history and studio work, relating design historical research to current practice. Design usually looks forward, anticipating what will come, and is less occupied with what has been. However, by neglecting design's legacy, one reproduces a decontextualised and dehistoricized practice (Fry, et al., 2015). In this respect, design history is an excellent means to engage with and reflect upon emergent practices and discourses, and to trace them back to their origins to get a deeper understanding. Or, as Meikle put it: "[...] a historical approach can indeed illuminate contemporary issues without directly addressing them [...]" (Meikle, 1995, p. 74)

At the same time, we have to prevent design history as a field of academic study from getting a 'strangely instrumental and legitimizing flair', as Fallan (Fallan, 2010, p. 25) criticised Dilnot's approach (Dilnot, 1984, pp. 3-20). The best way to avoid the common pitfalls of instrumentalising design history as a resource for designers, reducing it to the status of a quick Google image search is to teach design history in a constructive, non-authoritarian way, inciting students to ask questions and build up their own perspectives on the history and the legacy they are partaking.

Asking students for their opinion in order to challenge authoritarian knowledge as well as routinely conveyed, unquestioned teaching content, as a design educator Danah Abdulla (Abdulla, 2019, p. 9) suggests, is one possible way. However, students-led discursive redesigning of content requires that they have a sound methodological basis, either sociological and in terms of observational, ethnographic skills as in the first case, or historiographical as in the second case. Teaching methods are manifold, but one approach that many would agree upon is to empower students to obtain an active understanding of how the notion of difference in experiencing past and present worlds, or of the ways «history» as always constructed perspective into the past interacts with creative processes in general, and of design in particular.

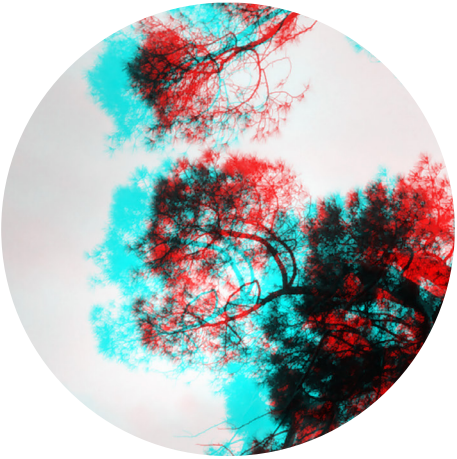
About the Authors:

Dr. Meret Ernst is a lecturer in design history and design theory at the Institute of Industrial Design and at the Institute of Aesthetic Practice and Theory at the Academy of Arts and Design in Basel and at the Academy of the Arts in Bern, MA Design. As a writer, she combines scholarly work with design criticism, promoting both her field and a climate of critical debate in it. In 2016 she initiated 'Design History Network' to promote the awareness,



research and mediation of design history in Switzerland. Currently, she is preparing a research project on the history of Industrial Design Education. – She finished her studies in Art History, Film and Media Studies with a PhD in Art history at Zurich University and began her career as assistant-curator at Museum of Design Zurich

Maya Ober is a designer, researcher, educator, activist, and the founding editor of depatriarchise design based in Basel, Switzerland. She works as a research associate at the Institute of Industrial Design and as a lecturer at the Institute of Aesthetic Practice and Theory at the Academy of Arts and Design in Basel. Her current research project "Space of radical possibilities – towards intersectional feminist pedagogies of design" at the Academy of the Arts in Bern is a multi-sited study situated interdisciplinary between gender studies, social anthropology, and design, exploring how intersectional feminist pedagogies influence design education.

Abstract | The paper describes a method of research and project developed in collaboration with the well-known food company named Barilla, which involved our Department in the elaboration of new concepts for their products. The name of the process is “adopt a customer” with reference to the close cooperation of the students with the consumer throughout the evolution of the project, from the survey to the prototype. In the first phase, the designer 'tutor' draws a broad overview of the person, to better understand the phase of qualitative collaborative research on the user's experience. The first results cross-referenced with the quantitative trends provided by the company, identify the needs and weak points to solve in the project. Everything is carried out in design for all perspective, trying to avoid exclusive elements and not to create too specific products. A continuous update would also ensure to offer a product in evolution with the needs of tomorrow's society.

KEYWORDS | DESIGN FOR ALL, ETHNOGRAPHIC RESEARCH, CO-RESEARCH, INCLUSION

1. Introduction

In order to develop marketing strategies and innovative solutions for their productions, major food companies work with the help of statistical agencies, which provide a countless number of data based on surveys. The main need of these companies would be to have eyes in the consumers' homes, to find out what people do and not say, how users spent time in real life, what are their daily habits.

The company that has commissioned us this research is Barilla, a leading company in the food sector and well established worldwide, which aims to provide to the end users a product which satisfies their needs. The request for several years has been not only to have new concepts for packaging and food but rather to understand how costumers use, consume, transport their products and, above all, which categories of users do not buy a product and why. Even if the company knows and possesses all the market data related to the purchase and consumption of their products, the macrotrends provides only a trend of a phenomenon in progress. Using these analysis, they do not extrapolate the causes and do not prefigure evolutions, which are essential elements to remain always contemporary.

The focus of this paper it's not on projects, these are the final results of the process conducted, what is important is the method designed to pay attention to the real needs of the customers. In fact, companies need to continually confirm their users' trust in a competitive and changing market. The radical changes in lifestyles, define new consumer profiles, so the packaging together with the product itself, must therefore, anticipate future trends rather than confirm the current or past ones. One indisputable trend underlined by Madhu V Swamy (2018) in the website customer think is the switch towards fresher, healthier foods. Customers are now more aware of the health benefits of the foods they consume and are actively looking for high quality products as a priority.

Forbes in 2019 shows the biggest trend driving the change in the food and beverage industry is transparency. Consumers want to know and understand what ingredients are going into their products, which is why we are seeing so many innovative products with shorter ingredient. Consumers are seeking for simplicity in addition to better quality foods. Before now, it was rare to flip to the back of a product on the shelf and read it before putting it in your cart. Consumers are reading the back of packages now more than ever. Clean labels with high ethical values are necessary, particularly to a growing segment of consumers with special dietary needs. Packaging has an important role to communicate all these elements: healthy, transportability, transparency.

Another one, in contrast, is that cooking meals and eating it is no longer a necessity. The number of people purchasing food to go, eating precooked food or ordering meals at restaurants has dramatically increased over the past few years. This had led to several new trends in customer's behaviour when it comes to food shopping.

"The novelty is these are no longer elitist choices, as happened in the past, but behaviours that affect a large number of people", says Montanari (2018) Professor of Medieval History

and Food at the University of Bologna in an article on Focus. These macro trends and data speak about numbers and masses of indistinct consumers, what is interesting for companies are the behaviours and lifestyles that products must accompany, in this competitive market: details create the difference.

The Packaging is the touchpoint between brand and customers, therefore values and necessities too. Packaging produces non only meanings (Ventura, 2014) as it names things, expresses concepts, gives information and evokes sensations, but it is also an object to use, hold, open and dispose of, thus suggesting gestures and habits that produce a consumption scene. The packaging attracts attention, informs about the past, production and content that generated the food and then becomes a means of future behaviours.

When this necessity of coherence and updating with users' trends is also associated to develop design solutions for the different target groups, the need to structure a design method emerges: the target and the brief change each time, the method doesn't change. Starting from a brief, the research team developed a method called 'Adopt a costumer', a mixed approach of Design for all and Design Thinking, tested in five consecutive years of collaboration with the company and applied to different brief on food and packaging.

The method is built on three different findings:

- target is just a starting point, it's like the focus in the picture, there is a whole blurred area that creates relationships and contrasts with the selected subject that generates a very interesting scenario.
- people are inconsistent, deny their statements with facts, unveiling a grey area between appearance and reality
- co-research/co-creation, the initial moment dedicated to the definition of the problem-setting is the most intensive part close to the user, where consumer guides the designer in understanding the scenario of the real problem to be solved.

2. Method

2.1 Target is just a starting point

Following to the quantitative market research, the Company every year select brief and target. The process of focusing on the target indicated by the Company, therefore, allows starting from investigating the reasons for the exclusion of other targets. We know that the moment of food consumption is often a convivial moment, where people interact and affect each other. This is an occasion to understand the shift or expansion of the selected target. The person who purchases the food, is not always the same person who eats, opens, transports and stores the packaging, and who cooks or customize it. All these components are elements of consideration, that lead to relate the initial target with others and combine

them in synergies that expand the scenarios for project. It's important to consider and observe who is choosing the food during purchase. There are different habits to consider: sometimes the consumer chooses for himself, other times for others. For examples, grandmothers buy for grandchildren, children shop for elderly parents, roommates sharing the meals. There are different habits of food consumption, frugal light and quick meals for some people, experimental cooking and rituals for others. It's important for the designer to understand when the brand chooses for the consumer.

The designer's task is to observe all the different behaviours during these interactions, moments of preparation and consumption. It's crucial to understand if someone is penalized by deficits in the opening or transport phases, or if a user refuses a food because of health problems or suspicion about the origin of ingredients used, or it is considered hypercaloric or low-caloric, or customer prefers another one.

Figure 1. Observation phase to find in packaging exclusions elements for users.

Design for all is the approach at the basis of this attitude, that avoids specialisms and focuses on inclusive elements. Design for All is design tailored to human diversity. The weaker groups of the elderly and children or those with debilitating diseases or allergies cannot choose some products or foods, or they are not satisfied by particular food categories that emphasize their diversity. They just want to choose their food as all the other people and they don't want someone else chooses for them. Design for All is described by the Foundation as the intervention into environments, products and services which aims to ensure that anyone, including future generations, regardless of age, gender, capacities or cultural background, can participate in social, economic, cultural and leisure activities with equal opportunities. Design for All/Universal Design should be implemented in all areas, because the human beings are diverse and everyone has the wish, the need and the right of being independent and choosing the own lifestyle without facing physical and social barriers.

These important requirements are investigated in the survey phase of existing products and then translated into new projects through the proposal of new openings, clear and readable

information, lighter and transportable formats, foods that can be customized according to diets and tastes, new opportunities within existing products. For project categories such as food and packaging the primary mission of design to improve people's lives becomes even more urgent. It is necessary to turn one's attention to reference targets during the project phase, in order to have more targeted offers, but without creating elements of exclusion towards other categories of users.

Another interesting resource to observe consumer targets from another point of view is also the food entry in social networks with the phenomenon of the #foodporn, it is a term commonly defines the practice of photographing and sharing on social media images of food, giving a lot of pieces of information about customizations, contests, interests. This is a very important phenomenon and at the time, for the word “food porn”, there are 19,500,000 results on Google, an entry on Wikipedia, a Facebook page with 2,713,143 like, 113,135,094 posts with the hashtag #foodporn on Instagram, and for designers it becomes an available data pool to watch carefully.

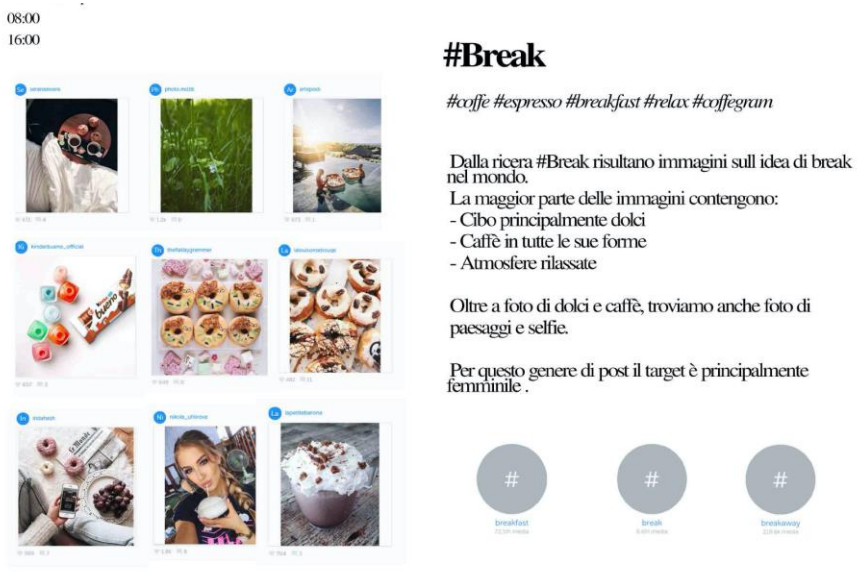

Figure 2. Foodporn research on Instagram conducted by different keywords

Yelena Mejova at the Qatar Computing Research Institute has analyzed the anatomy of the #foodporn phenomenon on Instagram for the first time in 2016. To get a global overview of #foodporn preferences, Mejova normalized the hashtag frequencies per country and then ranked the resulting foods. This list is dominated by foods with a high energy density, such as chocolate, cake, and so on. That allowed the team to explore the proportion of healthy to unhealthy dishes labeled #foodporn in each country. They did this by looking at other

hashtags associated with the food posts and by analyzing the sentiments they convey. By this reckoning, the most health-conscious country is the Netherlands, by contrast, Brazil, Argentina, and France have the highest rate of unhealthy tags. They found out that the rate of approval—of "likes"—is higher for healthy foods than for unhealthy ones. "The heightened social approval of healthy tags suggests that the community is already self-policing in promoting a healthier lifestyle," they say. As designers, who put proposals on the international market, we have to start seeing social media as a very interesting data resource, continuously updated and referred to a specific and localized users.

2.2 People are inconsistent

In the various surveys carried out over the years, we realised that quantitative, not in-depth data can be contradicted by qualitative surveys. Every year we start our research by organizing shadowing in supermarket, where students take pictures to the shopping carts of consumers, who choose the category of the product analysed, even of different brands. Then a quick interview to collect a large number of generic user profiles is done. The moment of purchase is just a fragment of a larger story that needs to be reassembled to give a more realistic picture of reality.

The quick and introductory search is followed by a slow and in-depth one that we call 'adopt a costumer' that varies according to the target audience. In this phase, we trace a specific and complete profile of the user, a sort of identity card that outlines the food, familiar and healthy status, with graphs and photos on the daily activities carried out to include personal passions and define a day in a life of character profile.

The researcher has to conduct a passive observation, a day in a life, very useful to expand the focus and to understand users in ordinary life: while they go about their everyday tasks, constantly passing from zoom out to zoom in, before entering into specifics of the product investigation. This approach helps designers to understand people's behaviour and context, to clarify how users behave backstage (Gouillart, & Sturdivant, 1994) in their home space, in their intimate dimension and environment where they feel comfortable. It is from here that the term 'adoption' and not 'interview' is born: to build trust between users and designers. In this kind of approach, users cannot hid anything, and they have to entrust their intimate reality to the researcher (Mulder, 2018). The process involves observation before collecting, interpreting and analysing data, leaving room for the user unexpressed needs, often hidden out of embarrassment about pathological and psychological disabilities.

Observations will be documented throughout the day using several methods such as taking notes, photographs, sketches or videos. These recordings often become evidence of user incoherence. In fact, if they are not asked anything they behave freely. On the contrary if targeted questions are asked, they are not always willing to tell the truth. These contradictions should also be considered in the analysis.

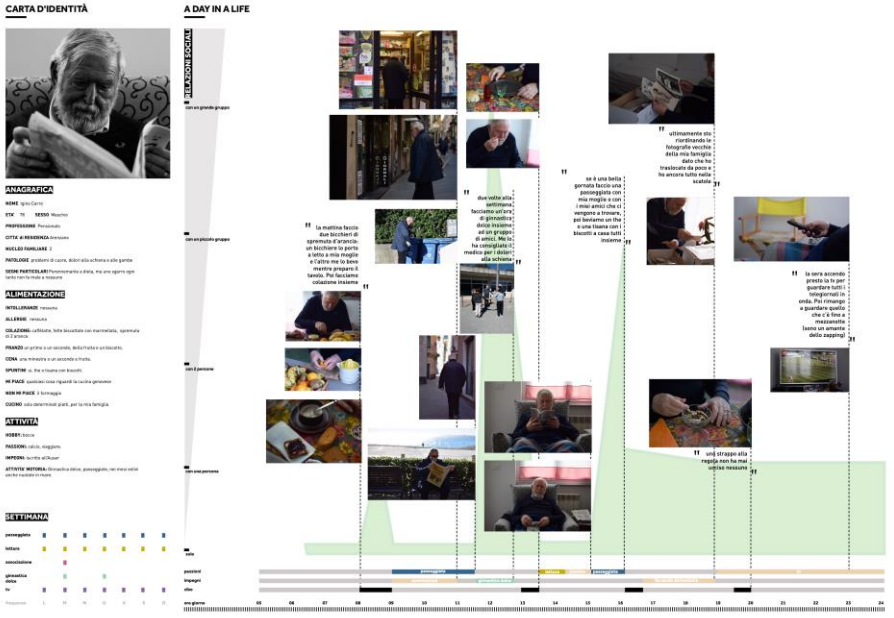

Figure 3. Identity card and A day in a life of adopted customer

Only later a specific topic is deepened through a specific and direct interview about the product of the investigation, packaging opening video, food experience and possible customizations of the product.

This is when it's very important to choose the right questions, so to set the problem in the right perspective. The 'adopted' shows the dynamics with the product to the tutor-designer, who knows the private dynamics and can understand the unexpressed needs and interpret them. Interviews take place in an easy and informal environment, to help users not to feel under interrogation. Despite these attentions, however, some inconsistencies emerge in comparison to the observation phase. For example, it happened that people showed an attitude of looking at sweets and snacks shelves during their shopping, but when directly asked they replied that they never purchase snacks nor eat outside the meals. At this point in the classroom, the storyboard is put in order, collecting all the data of the quantitative survey with the specific qualitative interview and outlining the personas taken as a reference target of the project. The personas are fictitious characters, created thanks to a combination of data that can represent a large sample of users.

Figure 4. Personas elaboration phase in classroom, as a result of realistic, specific and cross-references data

As they do not exist for real they are imaginary, at the same time they are very realistic because they are created on real data. The personas are generic, because they represent the average(s) of the data obtained and they are specific because they take some interesting details of some real people and raise them to a given meaning.This ethnographic research is the missing link between quantitative and quantitative data.

There's a reason why now, more than ever, companies are in desperate need of hiring anthropologists. It's not hard to understand why explain AJ Burt in Medium in 2019; in a world where everything is increasingly connected, everything is measured, and 97% of companies are investing in big data and AI, a question emerges: How do we consume, parse, and contextualize these massive datasets in a way that productively advances the goals the data was gathered to advance? The anthropology is an important resource, because it has been grappling with quantitative data and ways to make the best use of it for decades now, and certainly recognize the importance of context in analytical data and it can contextualize massive amounts of data about human behaviour.

Ethnography, based on anthropology, is a qualitative research study looking at the social interaction of users in a given environment. It provides the researcher with an understanding of how those users see the world and how they interact with everything around them. These types of approaches allow us to continuously cross-reference with different types of data and thus get closer to a real and coherent picture.

2.3 Collaborative Research is the intensive part of co-creation

The method of ‘adopt a costumer’ is based on an important phase of survey and research in close contact with the users, deepening and accentuating what in Design Thinking is defined as the phase of empathy through collaborative research. In a co-design process, the traditional roles change: the person who will eventually be served through the design process is given the position of 'experts of their experience', (Elizabeth Sanders and Pieter Jan Stappers, 2018) and plays a large role in knowledge development, idea and concept generation. Research collaboration is a deep and powerful research tradition that dates back beyond the recent emergence of calls for ‘co-produced’ knowledge. Co-design means that people come together to conceptually develop and create things that respond to certain matters of concern and create a better future reality, we think that the initial co-research phase is crucial. The project phase is still direct and managed by designer, while the research and post-design phase is in continuous dialogue and confrontation with the user.
At a most fundamental level, co-research is a practice where people collaborate or connect their knowledge, skills and resources in order to carry out a design task.

Figure 5. Moments of interactions and interview with users

This is the phase of the process in which an important connection with the user is established that allows you to observe, explore, listen, but above all to suspend any judgment. It is the phase in which designer and user work side by side, both on the same level.

The suspension of judgement implies a real exercise of reflection on what happens in front of us without elaborating solutions (Cristina Lavazza, 2018). The definition of empathy is the ability to be aware, understanding and sensitive to the feelings and thoughts of another person without necessarily having lived the same experience. Tim Brown (2009), describes empathy in design as a mindset, but also a fundamental cultural value that allows designers to develop innovative concepts, products, services, strategies and systems that respond to real needs and concrete desires of users. The adjective 'empathic' concerning design was introduced in the late 1990s (Battarbee & Koskinen, 2005) when companies started to realise that customers' responses on questionnaires were not enough to develop successful products (Leonard & Rayport, 1997; Sanders and Dandavate, 1999). When empathic design first appeared was described as a cultural change, because of the importance of emotion not only as a subject of study but also as a key attitude in people research.

Empathy offers palpable closeness to the other people, but it can also excuse experts from taking the broader view. As designers thinkers, we have the opportunity to step back from that singularity to consider the broader scope. The responsibility as designers should be not only to focus on the individual but to the society. Using the neuroscientific finding of "mirror neurons" (Rizzolatti & Craighero, 2004) as a biological evidence for the human ability of inner imitation, the simulation theory argues that we use ourselves as a model for the other person's mental life. This toggling between the individual and the group should be an ethical requirement for today's designer, and a principle introduced into the design-thinking rubric. A balance from individual satisfaction with system benefit, the unit with the whole, the happy customer with the enriched community. Empathy can help to frame the problem, but it takes an assertively creative mind to push ideas forward beyond today in the moment conceptualization.

Empathy is not the full story, is only one language.

While there has been significant attention paid to empathy within design literature, there has been little research on the nuances of lived experience or how to effectively integrate empathy and lived experience in co-creation. Empathy tools which involve working with physical objects or social techniques to get a sense of what users feel in their everyday life, by empathy maps, which help to visualize the experience of actors (Vink and Oertzen 2018). We become the link between the company and the consumer going into people's homes and filming them while they use and personalize the consumption of the reference product, we bring the company into the consumer's home and allow consumers to talk about themselves beyond the macro trends. Real design skill is about realizing that empathy is a small part of a much larger system of influences, causes, and effects on the situation at hand. Not only is empathy renewed and nourished throughout the process, with continuous meetings and comparisons on the interpretation of needs in concepts, projects and prototypes, and with tests and restarts for continuous improvement.

Design thinking isn't just about design anymore; it's about assembly, bricolage, sampling and appropriation. Not just craft and creation, but the bringing together of pre-existing elements

to build that which is new, and yet is not. It's important to create an open, collaborative, and connected process.

From this viewpoint, the empathic experience becomes the basic condition of disclosing intersubjective relationships and consequently grounding the sense of sociality. Nevertheless, the main difference could be synthesized in a shift from design 'with' empathy to design 'for' empathic experiences (Wendt, 2017).

3. Conclusions

In the era of rapidity of data and statistics that try to represent and visualize people's needs, in contrast, a slow and qualitative approach emerges. This is not seen in contrast with the quantitative method, but as a way to complete the picture, systematizing the automated spontaneity of actions with the weighted rationality of responses and statistics. Thanks to an immersive approach it is possible to understand cultures, needs, behaviours and develop responses that are more calibrated to the real needs of the user at the centre of the project.

The phase of investigation in close contact with the adopted costumers is followed by the design and prototyping iteration, in which the user takes part (in) of the development of the entire project, by continuous testing and comparisons, commenting on the effectiveness of the concept and the technical details of the project. The project takes into consideration the manifested and unexpressed needs of the users who represent sections of society. The designer becomes the tutor, the one who can observe carefully, dialogue, understand the unsaid wishes and interpret them.Every year the company asks us to redesign the packaging of a product and think about variations, we often put all these inputs together, and we ask students to reformulate the sensory experience of the user, intervening many more aspects related to gestures, new forms of sharing and lifestyles of the near future.

Design becomes not only a problem-solver but a careful investigator of the problem-setting, to translate the real needs and to promote a systemic design that knows how to relate the demand to a wider context, as a glue between innovation, accessibility and inclusion.

Abstract | As people grow older, their dependency on various services increases. However, these services are being progressively mediated by digital technology. Although scholars believe that technology adoption could enhance older adults' quality of life, little is known about seniors' sense of autonomy while using technology. In this study, we conducted ethnographic research including surveys and interviews to learn about seniors' technology usage in relation to their sense of autonomy. We used qualitative and statistical analysis to synthesize patterns and used our design research findings to inform our service ideation process. In the end, we proposed four major service design guidelines to help enhance the technology literacy of seniors: a changed mindset from singular problem-solving to pluralistic motivations, a meaningful learning process embedded in seniors' everyday communication needs, ongoing educational support within a sustainable system, and the value of integrating humanity with technology.

KEYWORDS | SERVICE DESIGN, AUTONOMY, DESIGN FOR SENIORS, TECHNOLOGY LITERACY, DESIGN PRINCIPLES

1. Introduction

With the rapid growth of the aging population around the globe, there is raising interest in improving the well-being of seniors by increasing their rates of technology adoption. The Institute of Aging predicts that adults aged 65 and older will comprise 20% of the United States population by 2030 (Ortman, Velkoff, & Hogan, 2014); similarly, in the Europe Union, the elder population is anticipated to be 25.6% (European Commission, 2014).

As people grow older, their dependency on various services increases. Approximately 12.7 million adults 65 and older, 40% who are 85 and older, live alone and often rely on social services instead of traditional family care (Klinenberg, 2013; Roberts, Ogunwole, Blakeslee, & Rabe, 2018). However, older adults' access to social services is hindered by the lack of technology literacy. Many essential commercial and public services are increasingly mediated by digital technology, which is not designed with proper consideration for seniors (Barnard, Bradley, Hodgson, & Lloyd, 2013). For example, some medical apps contain helpful functions to address the needs of older adults but are extremely difficult for them to access or use. In addition, seniors lack trust in digital services and are hesitant to seek technology support due to emotional barriers concerning their sense of autonomy (Ramdin et al., 2018). For instance, older adults are often afraid that they may be perceived as cognitively declining or burdensome to other people if they seek technological help. Therefore, in order for older adults to seek out technological support, their self-esteem and sense of control must be improved.

In this study, we conducted ethnographic research to understand the factors and patterns of older adults' autonomy in relation to technology, including a survey of 94 participants and 20 interviews. Using key insights from our research, we are designing a preliminary service system to support seniors' adoption of rapidly changing technologies, while maintaining their sense of autonomy. The service system includes workshops with board games, self-learning toolkits, and technology learning courses ranging from beginner to intermediate levels. Those tools and community-based courses will connect seniors with student volunteers, community centers, and local libraries.

2 Background

Technology literacy refers to the quality and state of educated competency in technology, representing a long-term exposure to learning while using. However, due to cognitive decline, lack of education, or discontinued updates the technology, seniors often have a hard time keeping up with major shifts of new technology (DiMaggio, Hargittai, Neuman, & Robinson, 2001; V. Hanson, 2009). Scholars in Human-Computer-Interactions investigate factors of seniors' technology adoption using the Technology Acceptance Model (TAM) with a focus on perceived-usefulness and usability (Davis, 1989). Researchers propose that designing technology for seniors should focus on direct values and ease of use (V. L. Hanson,

2010; Pan & Jordan-Marsh, 2010). These ergonomic factors empower novice elderly users who are learning technology, but multiple layers of barriers, including economic consequences of technology usage, fear of vulnerability, and distrust of data security, still slow the integrity of technology in seniors' lives (Hill, Betts, & Gardner, 2015). These concerns cannot be fully addressed from the perspective of TAM, because they are more associated with the ethical and emotional issues concerning the sense of autonomy (Fairweather, Shaw, & McBride, 2014; Perkins, Ball, Whittington, & Hollingsworth, 2012).

Autonomy generally means people's capacity to act upon free will instead of external pressure. Immanuel Kant (2011), representatively, describes autonomy as an active setting of self-imposed moral rules in contrast to passively being controlled by other people or the environment. Perceived usefulness of technology adoption generally refers to the worth of offerings (Cockton, 2005). However, if we consider the use of technology from the perspective of autonomy, the goal of technology is not just to attain external worth or reward, but to increase the possibility of actions with the support of technology. Studies show that the availability of alternative options influences seniors' ability to use technology effectively (Engel & Curio, 2010; Peek et al., 2016). If seniors rely heavily on family assistance in food delivery and transportation aid, there is less perceived usefulness when learning mobile food ordering and ridesharing services. In conclusion, seniors lack autonomy in using technology not because they have fewer options, but because they are not in an environment where technology literacy is encouraged.

In service design, Kim (2018) proposes a framework to understand varying notions of autonomy in relation to service participation, presented as layers: coproduction, argumentation, experience, and commitment. Coproduction refers to the cost-value benefit and reliable quality provided by the service. This concept highlights convenience and efficiency as people's sense of autonomy. From the perspective of technology, visual interfaces that improve perceived usefulness and usability are key to increasing the sense of autonomy in coproduction. When evaluating the effectiveness of different technology, Tele-Care, Hearing Aids, and Chat Robots have high positive effects on seniors' daily activities (Khosravi, Rezvani, & Wiewiora, 2016). These technologies are easily accepted because they offer direct value for seniors, such as lowering the cost of visiting the doctor or improving micro-mobility.

However, it should be noted that catering basic needs for seniors is not enough for transitioning them into an environment that cultivates technology usage. The second layer of argumentation demonstrates a co-creation process of service, where autonomy as a rhetorical power of communication and identity definition becomes important. As Web 2.0 emerges, user-generated-content platforms, such as YouTube and Wikipedia, have become popular. Users are given the power to shape content and media. Thus, technology enhances the involvement of user participation (Van Dijck, 2009). Networked technology is not novel, but participatory communication allows different roles of players to be involved with site support, senses of free will, and other reciprocal activities. Therefore, argumentation serves

a pivotal point in technology literacy by redefining the role of service receiver to service facilitators.

The third layer of experience refers to wholeness of service as an environment, where action capability is central to autonomy. People seek a causal understanding of what the service is, why to use it, what to get from it, and how to contribute to its development. Participation in experience resonates with the narrative interpretation of technology as experience. Interacting with the wholeness of technology is a sense-making process, comprised of expectations, connection to the environment by immediacy, perceiving reasons to understand causality, and appropriating the experience with personal meanings and sharing it with others (McCarthy & Wright, 2004). Only by encountering this input-output process do people meet their action goal with technology as a self-initiated rule.

The last layer of commitment represents participation as belonging to a social group or community with shared value, emphasizing autonomy as moral conduct. Examples of participation as thought have already been observed when people support, or boycott tech companies and their products based on their moral conduct and social responsibility. For example, when the media reported about the problematic leadership of Uber, some citizens organized action to boycott Uber and support its competitor, Lyft, instead, which would align better with some people's value systems.

In this study, we apply this framework of service participation—interpreted from the perspective of technology literacy—to pinpoint elder autonomy and identify different touchpoints to nurture autonomy. Most current technology interventions for seniors are still situated in the first and second layers, but as implied from our literature review, holistic support for autonomy requires consideration from multiple layers. Based on this framework, we conducted ethnographic research to understand the factors and patterns of elder autonomy and senior's technology usage in greater detail.

3. Methods

Our ethnographic research consisted of surveys and interviews with adults 65 years and older. The research protocol was reviewed and approved by the IRB. 120 surveys were filled out in 4 senior community centers in the Greater Boston Area. We excluded invalid surveys that contain incomplete answers and consecutive identical Likert scale answers, with 94 valid surveys remaining. Interviews were conducted with 20 seniors selected from the surveys, with consideration in recruiting for diversity in economic, racial, and cultural backgrounds.

In the survey, we included three sets of multiple-choice questions: demographics, lifestyle, and technology usage. We also included three sections using the 5-Likert scale, ranging from strongly disagree to strongly agree, to study the relationship between Autonomy, Participation, and Technology. Each session had 16 questions. Autonomy questions were

designed to progress from one's sense of independence to relational respect for others. Participation questions were designed to cover their competency in taking care of themselves as well as their engagement in community activities. Finally, technology questions asked about their familiarity with technological devices and their dependence on technology in their daily living.

After a quick reconnaissance of our survey results, 20 participants were selected for a one-hour follow-up interview. The interview consisted of semi-structured questions focusing on where, what, and how they attain and use technology, problems of technology usage, motivations and values that might inform the design, and their visions of future technology. This schema helped us to understand older adults' experiences with technology and helped us to construct scenarios for journey mapping.

3. Results

3.1 Survey analysis

To measure seniors' performance in three Likert scale sections, we added up answers of 16 questions in each section up to a total score of 90. Since the score distribution did not follow the normal distribution, traditional nonparametric tests were used to explore the relationship amongst different sections. Also, as the missing data in our survey was far less than 20%, we imputed all missing data with a person mean to maintain survey reliability (Downey & King, 1998). An exploratory factor analysis accompanied by cluster analysis was used to find out the main factors of the responses. The categories of characteristics provided us data for constructing personas with varying levels of technology proficiency and autonomy. Most of the statistics results were operated by SPSS 25.

All respondents were seniors over 65 years of age, with a median age of 77. There were 23 males and 71 females. Only 28% had a higher education. 53% lived alone and 17% lived with a spouse. The remaining lived with their family members in a senior home. There were other findings of their daily behavior and the use conditions of different kinds of technology, but to narrow down the scope of this paper, the following section will mainly discuss the analysis of categories of characteristics that had direct implications on our design research.

By comparing the median score among the three Liker scale sections, we learned that seniors performed highest in Participation with a median score of 70.81. Autonomy scored 67.00, and Technology ranked last with a score of 49.50 (Table 1). From the Spearman's rank test, the correlation coefficient between autonomy and participation is 0.706, while the correlation coefficient between Autonomy and Technology is 0.347 (Table 2). Although the correlation result did not provide a causal relationship between two variables, the weak correlation coefficient did tell us that current technology does not directly relate to seniors' sense of autonomy. However, a high correlation level between Autonomy and Participation

demonstrated that social participation, such as community events, promotes meaningful values for individual identity.

Personal autonomy is different from absolute independence. Sherwin states that for people who need assistance, their autonomy is more situated in the relationship with other social identities that support their agency of the self (Sherwin, 2011). Since technology is an important resource for assistant-living for seniors, we can bridge their sense of autonomy with technology through a high degree of social interaction, like creating a technology learning environment with communal support, reciprocal help, and other participatory activities.

Table 1. Descriptive Statistics of Autonomy, Participation, and Technology

		Percentiles		
Total score	N	25th	50th (Median)	75th
Autonomy	94	60.61	67.00	70.68
Participation	94	64.00	70.81	75.00
Technology	94	40.00	49.50	61.71

Table 2. Spearman's rho correlation coefficient test among Autonomy, Participation, and Technology

Section		Autonomy	Technology	Participation
Autonomy	Correlation Coefficient	1.000	.347	.706
	Sig. (2-tailed)	.	.000	.000

Exploratory factor analysis (EFA) is used to find patterns underlying the relationship amongst different variables. Therefore, following a normal EFA analysis procedure, first, we measured the internal reliability and validity of the original Likert scale data. With a score of 0.920 in the Cronbach's Alpha test, a KMO value of 0.680, and a significant result of Bartlett's test less than 0.01, the Likert scale data assured the fundamental requirements for using factor analysis. Although the result does not meet a perfect requirement for academic research, it is acceptable for design research (Beavers et al., 2013). After several iterations of principle component analysis, we removed 12 questions which contributed less to the main factors (items of which rotated loading value < .5 were suppressed).

Finally, 10 main factors with which initial eigenvalues are greater than 1 were retained, covering a 71.9% cumulative variance (Table 3). Factors were also interpreted by finding conclusions in their corresponding questions. After using K-means cluster analysis, we concluded that there were 3 main group characteristics among our participants. To balance the number of respondents in each group and avoid having any groups be too small, we first divided all factors into 6 cluster centers. After removing the 3 clusters that had a small number of respondents, 3 main groups were generated (Table 4).

- Group 1: Seniors are independent and have a lot of control over their own lives. They have no problems with daily activities and are quite good at using technology. This group of seniors performs well in all three sections. 44 people are in this group.
- Group 2: Seniors lack total control over their lives, but they can conduct their normal daily activities. Additionally, they actively participate in community activities and treat others with respect. This group of seniors is willing to accept other people's advice. 21 people are in this group.
- Group 3: Seniors have difficulty dealing with their daily activities and using technology. Their degree of basic participation is especially low. They may have a physical disability that influences their well-being. This may also lead to low engagement in other social interactions. 20 people are in this group.

Table 3. Main factors with corresponding questions

Factor	Item (Question index)	Factor description
F1	P6, P13, P9, P7, P16, P8, P11, P5	Seniors are leaders in their community. They are willing to listen to others also give people advice.
F2	A14, A15, A16, A9, A13	Seniors are confident. They treat other people with respect while earning respect from others.
F3	T3, T2, T1, T4, T10, T14	Tech-savvy seniors. They are confident and proficient in using technology devices.
F4	T13, T12, T11, T14	Seniors are positive about learning new technology.
F5	P4, P2, P1, P3	Independent seniors. They have no problem doing household chores and other daily activities.

F6	A3, A4	Seniors have significant control of their lives and there is little that can interfere with their decisions.
F7	P14, P15	Seniors actively participate in community events.
F8	T6, T8	Seniors are confident about finding accurate and useful information.
F9	A2, A1	Seniors are flexible and positive throughout their lives. They live happily and do not worry much.
F10	T16, A12	Seniors are comfortable accepting assistance from others.

Table 4. Main group characteristics

Factor	Group1	Group2	Group3
	N=44	N=21	N=20
F1	.08850	-.12568	.32049
F2	.11806	.35683	.18739
F3	.35715	-.17207	-.78806
F4	-.12242	.10601	-.06915
F5	.48614	.30149	-1.17185
F6	.54192	-1.29074	.14318
F7	-.03253	.48803	-.35015
F8	-.08553	.15604	.26698
F9	.09591	.04766	-.25189
F10	.13898	-.22185	.29364

3.2 Interview analysis

From the 20 interviews, we summarized factors that may hinder technology adoption and others that facilitate learning new technologies. The layers of service participation in autonomy are used to categorize these factors below (Table 5).

Table 5. Barriers and facilitators of technology adoption for seniors

Layers of service participation	Barriers	Facilitators
Co-production	Lack of accessibility, Low-cost performance, Language barriers, Lack of simplicity	Voice-controlled technology and other convenient means, Excitement towards learning, Helpful teaching
Argumentation	Lack of ongoing education support	Friends and family members, Connection with the online community
Experience	Distrust, fear, discouragement, and other negative feelings	Confidence, pride, and other successful feelings
Commitment	Personal stubbornness, "Old-fashioned" ideas	Positive attitude including open-mindedness and eagerness to learn

In co-production, lack of accessibility turned out to be the main problem. Seniors' mobile devices have features such as increasing the font display size, but these settings are deeply hidden in the operating system, and seniors are commonly unaware of them. Additionally, technology terms and slang are unfamiliar to novice senior users, adding difficulty to learning. Seniors can often get free smart devices from social services or used devices from their family members, but learning the skills required to use these devices requires cognitive effort (Fitts, 1964). Although seniors often say that voice-controlled technology, like the Amazon Echo, is convenient to use, their motivation can quickly drop due to a lack of basic technical knowledge required to interact with voice-controlled assistants, including terminology, grammar, and actions. There is definitely a need to design courses that can teach them the fundamental basics of technology in a simple and low-cost manner.

Since it takes time for seniors to gain autonomy in the co-production level, we should aim to design services for the argumentation level earlier. The main aim of designing services for this level is to change the mindset of senior learners and their educators away from viewing technology education as one-off problem-solving. Instead, a more meaningful strategy for

co-production is to grasp a broad understanding of what technology is and what it could be (Shuell, 1990).

In particular, there is a need to design tasks for seniors that vary based on their personal situations. For example, it would be beneficial to make a connection between technology and seniors' relational needs with family or friends in order to enhance communicational autonomy. Meaningful interpersonal interaction already exists, such as a technology learning program with local high school students in which the older adults' relationships with volunteer students were a key motivation for the seniors to continue their participation. However, an issue here was the lack of continuity beyond sporadic interactions. It is noted that service for seniors must integrate a systematic plan for continued learning and personal connections.

The issues in the layer of experience are negative emotions such as distrust, anxiety, and fear surrounding technology. One participant who was a doctor before retirement described the emergence of the electronic medical record (EMR) as a "nightmare for doctors"— a system that hindered the interactions between doctors, patients, and their environment. As Dewey (2005) said, having an experience is to undergo the process where the subject and the object mutually adapt, ending with a balanced relationship which leads to the sense of autonomy in action possibilities. When social interactions are replaced by data and machines, the agent can easily lose the causal relationship of the whole. As noted by McCarthy and Wright (2004), unfolding the invisibility is to create meaningful movement in each step to turn invisibility to visibility by the narrative structure. The implication for design is to break the complexity of technology into an organic flow that helps seniors' learning processes with gradual steps, a clear sense of goals, and action plans that can give the seniors a sense of growth and positivity.

Another observation was the seniors' tendency of viewing technology from a moral perspective, which can be interpreted as a commitment to social values. Some of our interviewees expressed a strong unwillingness to learn technology because they believed technology would replace people and "take jobs away," thus being morally problematic to the community. Others have a positive view of technology, less because it enhances their lives, but more for the greater wellbeing of the community. For example, one person described the future of technology as "something that enhances humanity". Therefore, seniors' commitment to learning technical skills needs to also address the aspect of value-judgment and contribution to the larger society, which will, in turn, empower them with self-esteem, autonomy, and dignity.

4 Preliminary Service Design

Based on the outcome of our research, we are in the process of designing a service with multiple components, including workshops with board games, self-learning toolkits, and technology learning courses for beginners, intermediates, and expert level users. We

presented this idea to Peabody Properties, Inc., a real estate company that runs fifteen senior living homes in Massachusetts, for a partnership to test the design. Our community-based courses and tools will connect seniors with themselves, students' volunteers, community centers, and local libraries. In this paper, we will share the early phase of the design by introducing the models that we have created.

We first synthesized the survey and interview outcomes into three personas with basic information, conditions of technology use, frustrations, as well as pain points in service participation (Figure 1). The personas reveal that the technology education service needs to consider different levels of users: beginners who need to learn technology from scratch, with low motivation and a greater need for support from their peer group; intermediate users who are familiar with the basics, but require a firmer connection between technology and their daily life, and assistance for fixing issues that come up; and lastly, advanced users who are highly motivated to continue self-learning and to help other seniors. With these personas, we developed customer journey maps that show a typical scenario of the current experience analyzed with the four layers of participation (Figure 2). We then mapped the scenarios of a proposed new experience on an applied version of a service blueprint addressing barriers and fears, different stakeholders of technology services, and services and mediums based on various motives (Figure 3).

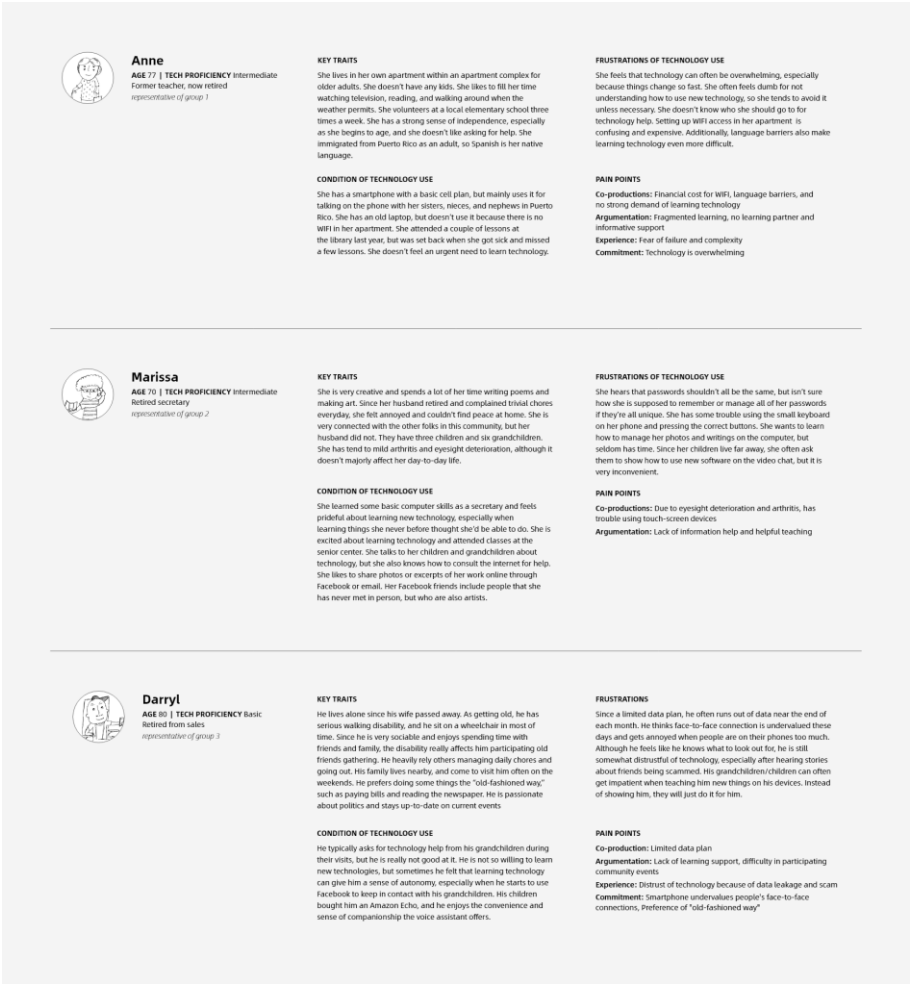

Figure 1. Personas

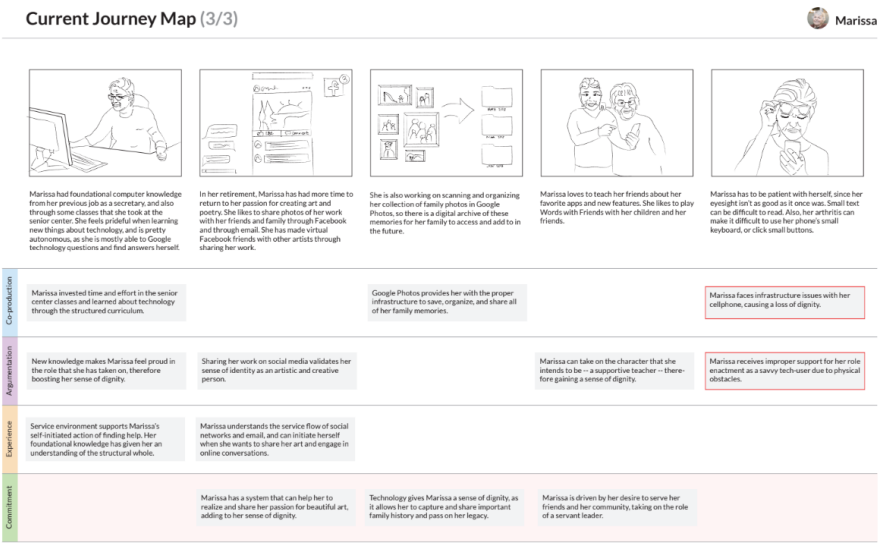

Figure 2. Customer Journey Map

Figure 3. Service Blueprint

After organizing our research findings and brainstorming ideas through these models, we came up with key service concepts for each layer of participation.

- Co-production: we propose “providing control affordances” and “creating a backdoor for seniors” as ways to teach the basics and to provide affordable maintenance tactics. “Control affordances” refers to intuitive interfaces that bridge the analog and the digital and have icons and terminology with clear meanings. A “backdoor” refers to learning how to find additional help, such as customer service or tutorials.
- Argumentation: the strategy of “improving connections” and “promoting participation,” which means teaching seniors communication-oriented digital services through a series of entry-level tasks in order to improve their connections with family and friends. These tasks will be embedded in the participatory workshop for social engagements between the seniors. Learning technology as part of the tasks that older adults are likely motivated to perform will situate technology literacy in a contextual learning process.
- Experience: the main goal is “relieving fear and invisibility” and “enabling self-guided services.” We aim to use checklists to categorize different failures and create board games with visual manual guides to remove anxiety. We will also provide take-home toolkits to motivate self-guided ongoing learning.
- Commitment: We propose “making connections with the community” and “contributing to other seniors,” including group activities, family or local volunteer engagement, and mentorship opportunities for expert-level seniors. Additionally, community-based drop-in services are also proposed to provide regular technology support.

Our service system integrates these service concepts above into three components (figure 4). The first is offline classes with group activities and games, which are provided by volunteer students and community facilitators with teaching tactics. The second is a mobile application and take-home toolkit which supports technology-learning resources and tasks and progress checking. The last is office hours as a “backdoor” for supporting seniors’ urgent needs regarding technology issues, as well as providing another opportunity for them to foster their sense of connection with the community. In developing each of these components, we will focus on basic affordance and control, communicational autonomy, a meaningful and gradual learning process with a clear sense of goals and action plans, and the social value of learning technology to contribute to the community.

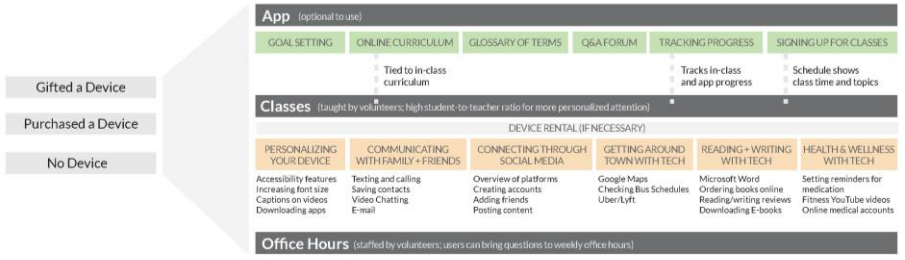

Figure 4. Service System

5. Conclusion

This paper outlines a design research process for a service to improve seniors' technology literacy. We conducted an ethnographic study and used models of analysis and synthesis, using the theoretical framework of autonomy and participation. Sustainable and systematic technology education for seniors needs considerations from communicational, emotional, and communal aspects, in addition to functional support. Humane and reciprocal services will further empower their autonomous living. In the next phase of our research, we will continue to develop the components such as the content of the class, board games, apps, and take-home manuals.

We conclude with three implications for designing a technology intervention for seniors. From the perspective of coproduction and argumentation, there is a need to shift the focus from one-off problem-solving and interface usability to a broader context of why seniors learn technology and how to motivate them. From the perspective of experience, the process of learning needs to be gradual, systematic, and holistic— embedded with meanings that are relevant to senior's everyday life and community engagement. The final aspect is technology literacy's connection to the larger society and humanity. Enhancing the humanity of technology use not only improves the commitment level of service participation, but also facilitates the pluralistic mindsets for effectiveness in learning new technologies.

About the Authors:

Houjiang Liu is a design researcher in the Center for Design at Northeastern University. He holds an MFA in Design from the College of Arts, Media and Design at Northeastern University. Houjiang studies technology adoption and human urban interactions through design and human-computer interaction.

Miso Kim is an assistant professor in the Department of Art + Design at Northeastern University. She holds a PhD in Design from the School of Design at Carnegie Mellon University. She studies service design through humanist frameworks. Specifically, she is interested in studying dignity, autonomy, and participation in service design.

Canqun He is a professor in the College of Mechanical and Electrical Engineering at Hohai University. She holds a PhD of Engineering Psychology from Zhejiang University. She studies human-computer interaction and product usability evaluation with nearly 80 academic papers published.

Tia Thomson is an associate at Visible Hands VC. She works on bringing service design to increasing community involvement and improving access and equity for marginalized communities. Topics include youth civic engagement, volunteer management, and education access.

Acknowledgements: we gratefully acknowledge the support from Peabody Properties and Boston Public Libraries for recruiting participants. The project is funded by Research Collaborative Grant, Student Grant of Research, Scholarship and Creative Activities from the College of Arts, Media and Design at Northeastern University and the 2019 Social Science Research Grant from Jiangsu Province.

Bio-revolutions: radical change, design cultures and non-humans

Carolina Ramirez-Figueroa[a], Luis Hernan[b]

[a]Royal College of Art, United Kingdom; [b]The University of Sheffield, United Kingdom

Abstract | This paper explores the interface between culture, design and biology. It draws on methodologies and existing literature on Anthropology and Science and Technology Studies to argue that despite predictions of biotechnologies bringing about revolutionary change in design disciplines, there is a risk of bio-design becoming a 'failed' revolution, similar to that of personal computers. To counter this, we introduce the biomaterial probe, a methodology that enables designers to find potential opportunities, challenges and limitations of introducing living systems in the practice of design.

KEYWORDS | BIODESIGN, BIOART, DIYBIO, SYNTHETIC BIOLOGY, BIOTECHNICAL, BIOTECHNOLOGIES

1. Introduction

In July 2017, Stella McCartney issued a press release showcasing her collaboration with Bolt Threads, a biotechnology company specialised in textile materials derived from naturally-occurring fibres. Prototypes followed a year later of a *Falabella* bag using Mylo, a biomaterial derived from mycelium, the filamentous, branching structure generated by fungi and bacterial colonies. A scaffold of corn starch is used to provide sustenance to mycelium, and once the filamentous structures have grown and depleted the starch, it is put in an oven resulting in a compact, dense fibre. Mycelium-derived materials have become a standard bearer of the biotechnical revolution in design, with designers and technologists developing commercial applications of the biomaterial, ranging from packaging to furniture to textiles.

The cultural semantics of the Mycelium Falabella is worth exploring. The Falabella was introduced in Stella McCartney's 2010 winter collection, modified and updated regularly since gaining a fashion item status among actresses, socialites and so-called 'it-girls'. Mycelium-derived materials gained popularity with the inclusion of Mycotecture in the 2014 MoMa exhibition 'Design and Violence' curated by Paola Antonelli. The piece, developed by artist and teacher Phillip Ross, is an arch assembled of bricks produced by mixing sawdust with Ganoderma lucidum, a fungus species that metabolises and transforms the wood into a fibrous material (Antonelli et al., 2015). The Mycelium Falabella was also produced to feature in an exhibition, this time organised by the Victoria and Albert Museum in 2018: *Fashioned from Nature* (Ehrman and Watson, 2018).

Four years apart, the use of the material in both pieces signals an evolution in its cultural status: from a promising material to desirable product inscribed in a wider narrative of environmentalism and ethical consumption, signalling an innovation cycle that heralds a long-awaited revolution triggered by a design-led 'bio-economy'. Here we argue that although mycelium and others offer clear technological improvement over traditional technologies, there is a risk that the long-heralded bio-economy and bio-design results in a failed revolution. We draw an historical parallel to the development and evolution of personal computers to suggest that the potential of biotechnologies for radical change depends on the capacity of designers to give them meaning: to construct frameworks of reference and present their artefacts in culturally meaningful ways. Doing so requires slowing down and detaching from explorations that begin with a logic of substitution, in which living systems are scoped as the 'green' alternatives to 'dirty' technologies. We present biomaterial, provisional strategies and tactics that enables designers to explore the potential opportunities of the design of living matter. We explain the use of biomaterial probes in an open-ended exploration, revealing the way different actors and non-humans, ranging from institutions to microorganisms, align to facilitate or block design.

2. Living matter and design of the living

Development of mycelium and other similar materials is inscribed in a wider discourse of *biotechnical* design (Ednie & Brown, 2013). The last decade has seen a growing body of theoretical and creative work, a *biotechnical discourse*, which operates on the premise of using living systems as part of the design and fabrication of artefacts. The biotechnical discourse is prefigured by existing traditions — there is, for example, a long-standing tradition of biological analogy in architecture that stretches from Ancient Antiquity to the Renaissance, to Modernism (Steadman, 2008). Caroline Van Eck (1994) suggests there is a continuous theme of imitation of nature that, she proposes, can be described as an alchemist's quest: a desire to transmute the products of technology — dead matter — into living beings. The alchemist quest can be traced throughout history, from Classical antiquity and the Renaissance's use of living systems as source of eternal principles of beauty and order; to the way that *On Growth and Form* influenced the work of Mies Van Der Rohe, Alvar Aalto and Frank Lloyd Wright. The biotechnical discourse however stands apart in its aspiration to use biological systems directly, as a form of *living matter* (Catts & Zurr, 2014; Ednie & Brown, 2013; Telhan, 2016).

To understand biotechnical design, it is important to review the evolving narrative of biotechnologies themselves. Contemporary discourses in biotechnologies, led by synthetic biology, aspire to reduce the complexity and randomness of living systems (Breithaupt, 2006). Broadly speaking, there is an idea of reducibility connected to notions of parts, systems, and wholes, that are related to the modification of existing organisms and the creation of entirely new ones (Schyfter, 2011). In parallel, citizen and enthusiast movements have engaged with the tools and methods of biotechnologies, infusing them with an ethos of democratization. Movements like DIY-Bio have made working with living systems widely available to non-experts (Seyfried, Pei, and Schmidt, 2014; Meyer, 2014). The combination of approaches and traditions around biotechnologies has motivated the emergence of a biotechnical discourse in design. The development of biotechnical design has created the conditions to trigger substantial opportunities for innovation and for a nascent bio-economy sector in design. Design-led efforts are underway to produce zero-emission bricks through bacterial fermentation (Dosier, 2011); bacterially-augmented concrete that repairs itself (Jonkers, 2007; Jonkers et al., 2010); alternative industrial methods to produce dye through bacteria (Chieza, 2018); and faux-leather synthesised through bacterial metabolism (Bain, 2017). These initiatives join a much-hailed 'biological' revolution that is often compared to the 'garage movement' of personal computing in the 1970s (Landrain et al., 2013; Peccoud, 2016).

2.1 Technocentrism and substitution

Biotechnologies make possible new materials, often integrating living and semi-living matter, which offer considerable advantages over existing technologies. These new technical possibilities, however, are also a good opportunity to reflect on whether talk of an upcoming revolution is warranted, and to what extent the current cultures and practices of design support radical change. If we accept the proposition that living matter represents a fundamental change from any form of material or technology ever used in design, then there is a risk of understanding the new using the framing of the old.

A relevant analogy here is *horseless carriage,* the name given to cars when they had been first released to the consumer market. As a radically new form of technology, users would often refer to cars in reference to horse-drawn carriages, a form of technology they were familiar with. Cars were similar in that they fulfilled the same function, acting as a form of transport to get users from point A to point B. Used as an analogy, the phrase describes the "shifting perception of a practice as it transforms in relationship to a new technology" (Chastain et al., 2002, p.239)

2.2 Bio-revolutions

The risk of framing the new using the terms of the old is illustrated by the development of personal computers in the 1980s and 1990s. Bryan Pfaffenberg (1988) suggests that innovators are often constrained by social processes. Following a social constructivist understanding of technology, he rejects the notion that technological innovation is driven by market demand and, instead, suggests that for technologies to 'succeed' in the market and be adopted by large numbers of people, innovators need to construct *meaning-frameworks*: a narrative that present their innovation as responding to a need that didn't exist before. Pfaffenberg draws on the notion of the heterogeneous engineer to suggest that innovators do not only manipulate technology, but also change the social world in which the innovation is meant to be inscribed. In doing so, they create new frameworks of social roles, meanings and values.

Pfaffenberg analyses how the success of the personal computer in the 1980s was influenced by the meaning-framework of its creators. Early innovators hoped personal computers would "equalize opportunity for all races, creeds, minority groups, social classes — even help save endangered species" (Bunnel quoted in Pfaffenberg, 1988, 41), influenced by disparate movements such as phone phreaking and the hacker ethic. Phone phreakers emerged in the late 1960s as a subculture influenced by the counterculture movement whose members counted technically minded people sharing an aesthetic interest in the complexity of phone networks. One of the most visible members of the movement, Captain Crunch, famously epitomised the movement when he managed to break into the international phone network to connect a call, made from a phone booth in the California Livermore Valley, and that passed through numerous exchange centres including Tokyo, South Africa and Brazil before reaching the phone booth next to him. The motives of Captain Crunch coincided with those

of another subculture emerging in parallel to the phone-phreakers, the hacker movement. The Captain wasn't so much interested, according to his own account, by the ecstasy of gaining control of a technical system; his motives were driven by a desire to learn about a system. Breaking into the system, however, was a transgressive act. He wanted to point out to 'Ma Bell', the colloquial name for the Bell Telephone Company, the many issues and weak points of their telephone network. He didn't want to "screw Ma", he wanted to "show Ma Bell how good I am. I don't want to screw her, I want to work for her".

The motivations of Captain Crunch — a wish for recognition and approval mixed with an aesthetic pull to technology — would be reformulated in *Computer Lib*, the 1974 publication that came to epitomise the hacker ethics. The author, Ted Nelson, makes an argument to demystify computers and promote a form of computer literacy, enabling laypeople to familiarise themselves with the principles of hardware and software operation. For Nelson, the way that computers developed and were understood by the public had a highly political dimension, insisting on the need to decentralise computers, a technology that had been centralised by big corporations such as IBM. Phone phreaking and the hacker ethics were highly influential in the development of early personal computers. Steve Jobs and Steve Wozniak, co-founders of Apple, famously assembled and sold 'blue-boxes' from their dorm: electronic devices that enabled their owners to break into the telephone system in the same way that Captain Crunch had done a few years before.

The meaning framework of phreaking and hacking cultures enabled early innovators to frame the personal computers in terms of a democratization of technology; they would make accessible to 'the people' tools that had so far been used for commercial gain and military purposes. Despite the hopes that the new form of technology would promote creativity and autonomy, market pressures and corporate interests meant that personal computers would end up targeting white-collar workers, professionals, and technical specialists, sectors which had already been benefited by older forms of computers. Later innovations, such as networking technologies, would consolidate this trend by making 'personal' computers less so, connecting them to larger (and often corporate) mainframes and servers. More contemporary advances, such as the much hailed 'cloud computing', would seem anathema to Nelson's cry to move away from centralisation and to hand control back to the people.

2.3 The living and radical change

Historical parallels are always imperfect — there is a danger to try and see forwards in the same way that we narrate in retrospect. It is, however, possible to argue that biotechnologies risks following the same path that personal computers. On a superficial level, both technologies involve innovations that are not fundamentally radical, but that instead repackage and make more efficient existing techniques and tools. There is a deeper connection between biotechnologies and personal computing, operating at the level of their design cultures.

The genealogy of biotechnology, and especially of synthetic biology, is often contested but practitioners in the field often locate the development of the personal computer and digital technologies in the 1980s and 1990s as a foundational point, inheriting their ideology and meaning-framework (Cameron et al., 2014). A good example is the name of the discipline itself. Drew Endy, Rob Carlson and Roger Brent, often identified as the 'founders' of synthetic biology, often referred to their initial efforts as an 'open-source biology', describing it as effort to establish a culture of sharing among developers. The design principles of synthetic biology — abstraction, standardisation and modularity — are often explained by drawing analogies to the way computer engineering isolates hardware (the substrate that enables computation) from software (the set of instructions that describe calculations, and how these should be interpreted). The aim is to generate design approaches that require no expert knowledge, in the same way that the personal computer made it possible for some people to develop software without specialised knowledge of computational logic at board level.

The slippages in drawing analogies to personal computers generate also a fluid exchange of meaning-frameworks and conditions innovation and action of biotechnologies. A good example is the arsenic biodetector project developed initially by the 2006 University of Edinburgh iGEM team, a student-led competition that has become an unofficial conference for Synthetic Biology. The project aims at producing a low-cost, easy to use detector for areas known to be prone to groundwater well pollution in Bangladesh. It involves an arsenate-responsive promoter which, when inserted in bacteria, enables expression of genes that change the pH of growth media, providing a colour-coded signalling of arsenic presence. In a close parallel to the phone-phreaking and hacker culture, the narrative of the project is suffused with references to a 'democratisation' of technology and a commitment with marginalised communities.

Despite good intentions, the arsenic biodetector is a good example of the risk that biotechnologies run of using counterculture as little more than a punchy slogan. Cristina Agapakis reminds us how the problem of arsenic contamination stems from humanitarian response efforts in the 1970s to provide water for Bangladesh. The design of the tube-wells, combined with political and social issues, ended up generating a public health catastrophe. Although the low-cost bio-detector would be, at first glimpse, a welcomed tool and a potential step towards solving the problem of arsenic contamination, it is also problematic in the way that it is framed and the ideology that animates it. Agapakis writes:

> "inexpensive diagnosis of arsenic contamination will not be able to address the underlying problems of water infrastructure and management in Bangladesh (…) this history demonstrates that looking at complex problems through a narrow, reductionist lens can lead to harmful designs with dangerous consequences." (Agapakis 2014, p.125).

Just as the personal computer was intended to empower marginalised communities, projects like the arsenic biodetector risk becoming technologies that offer some advantages over existing technologies but which stop short of fulfilling their 'revolutionary' potential as they end up targeting the same users and applications than their predecessors. From an innovation perspective, the slippage between meaning-frameworks encourages narratives of substitution and remediation, in which organisms are used as enhancement in existing processes. It also influences a design culture driven by technical possibility, having as point of departure the current state of the art in the laboratory and working backwards from there to try and fit a context of application. The combination of a substitution logic and a technocentric exploration makes it more difficult to imagine a path for these new technologies to influence radical change in design disciplines and are the implications and challenges these might bring.

3. Biomaterial probe

The example of the arsenic biodetector suggests that are several factors that have promoted the slippage between meaning-frameworks and design cultures between the personal computer and biotechnologies. From the perspective of designers however, one main issue is imagination — given the fact that designers often have limited knowledge of living systems and the techniques to work with them, their capacity to imagine their possibilities are constrained to substitution and remediation of existing technologies.

The *Bio-material probe* is a set of design tactics intended to provide a means of exploring a design space, rather than to enable a design context which, in a more traditional context, would entail working towards specific objectives and producing tangible outcomes. Instead, bio-material probes provide the setting in which it is possible to engage with biological systems from a design perspective. The term is inspired by the work of William Gaver, Antony Dunne and Pacenti (1999), and by *derives,* a technique promoted by the Situationist International to highlight the influence that geographical environment, and especially urban settings, have on the feelings and behaviour of people (Ford, 2005; Debord & Knabb, 2014). *Dérive*, translated literally as drifting, consists in suspending normal motivations to movement in cities and, instead, allowing themselves to be *attracted* by the terrain, operating as a sort of probe that is being influenced by the forces at play in urban environments. In the context of the Situationist movement, *dérive* emerges as a reaction against the average experience of cities, which they perceived as limited. The *dérive* is intended to *throw* people into the cities, allowing change to force them into situations they would otherwise rarely encounter (Debord, 2006).

Likewise, *bio-material probes* are intended to *throw* designers in the context of biological work, generating situations where assumptions and the status quo can be challenged. As an active element, they give designers a reason to explore biological systems. They are not oriented to practical applications, but rather to exploring the context, activities and

economies involved in the work with biological systems. A good analogy to describe the bio-material probe is to characterise it as a recipe for how cakes are made. It enables understanding the context, materials, technology and other assemblages which enable the cake to be made. It doesn't, however, provide a prescriptive recipe for doing a specific cake. It enables a practitioner to locate themselves in the context of biological work and, as a methodology, provides purposefulness without being tied to a specific design outcome.

3.1 Biomaterial probe in action: Bacterial Assemblages

Bacterial Assemblages is a project that explores notions of self-organisation and complex systems by engaging with form generation in bacterial colonies (see Figure 1). An earlier exploration proposed the State-Space of design, a framework to approach biological systems in design contexts. The term is derived from its use mathematics to describe the configuration of dynamic systems in terms of key variables, and a set of equations that describe their behaviour and interconnections. A state-space representation consists of a graph whose axes are the key variables, and where the *state*, or the possible configuration of the system at any point in time, can be represented as a vector.

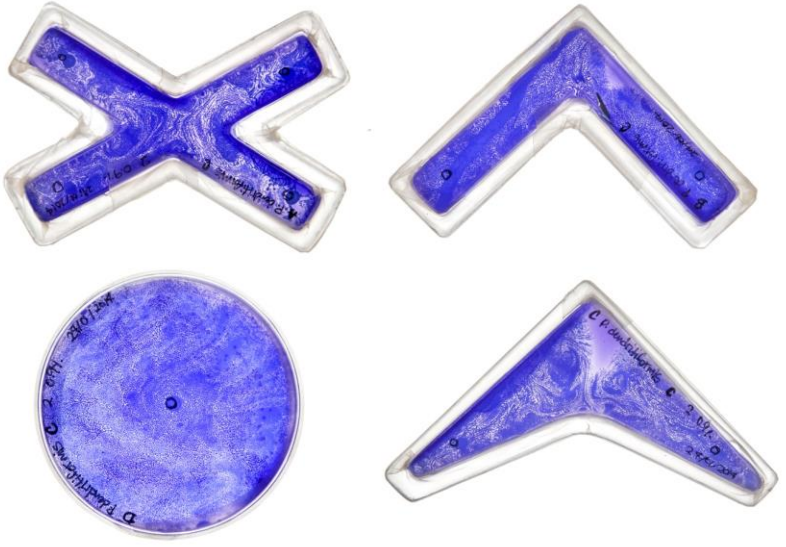

Figure 1. One of the experiments developed as part of Bacterial Assemblages. Petri dishes are custom made to influence the physical 'state-space'. Chemical conditions are altered by changing the composition of the growth medium. The growth patterns are developed by Paenibacillus dendritiformis C morphotype, Paenibacillus vorte, and Paenibacillus dendritiformis T morphotype

We defined three state-spaces which influence biological form: cellular, chemical and physical. The cellular state-space is defined by the boundaries of the cellular membrane, and it is used to define all the processes that take place within it, including, for example, DNA transcription and translation, as well as protein production. The chemical state-space refers to conditions in the environment, such as pH levels and nutrient concentration, which are thought to trigger specific sections of the genetic code that result in the development of form. Finally, the physical state-space includes the physical forces and energy within the environment and that are often confined by the agar plate such as the temperature of the growth environment, and the physical structure of the agar itself.

Bacterial Assemblages suggested that, in addition to the original state-spaces, there are also contingent aspects of working with living systems which are crucial in accounting for the interaction between living systems and human designers and that had an important effect on the design outcomes that result of this exchange. The original model of three state-spaces is expanded to include three further spaces of contingency: *spaces of practice, cultures of crafting* and *social interactions. Spaces of practice* refer to the way that the spatial configuration of workspaces and tools conditions the development of activities, in the way they embody a specific script that refers to different frameworks of knowledge. *Cultures of crafting* concentrate on the frameworks and techniques that enable things to be done within disciplinary boundaries. *Social interactions* refer to the governance of spaces that enable certain things to happen, and which depend on exchanges between individuals.

Figures 2 to 4 show some of the diagrammatic strategies used in *Bacterial Assemblages* to reveal and analyse the spaces of contingency. The influence of institutions, epistemologies, spaces and social interactions are difficult to trace directly to the development of bacterial form, like the one shown in Figure 1. These diagrams, however, operate as a form of provisional cartography

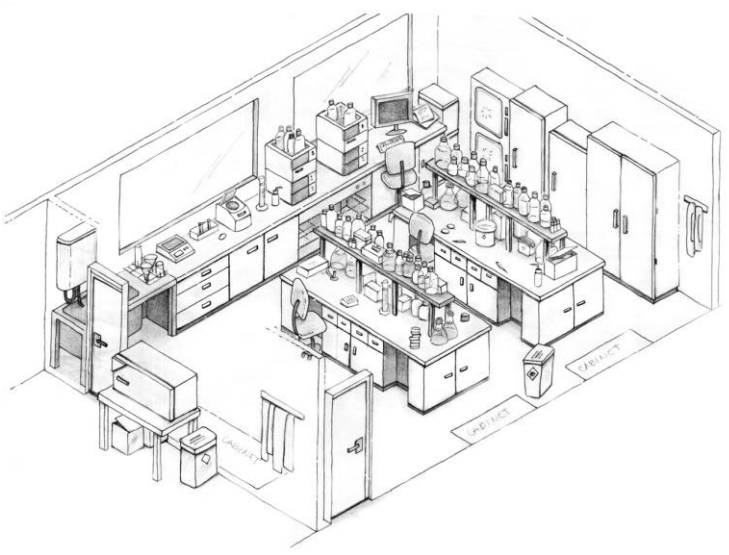

Figure 2. Isometric diagram of the main microbiology laboratory used in the exploration.

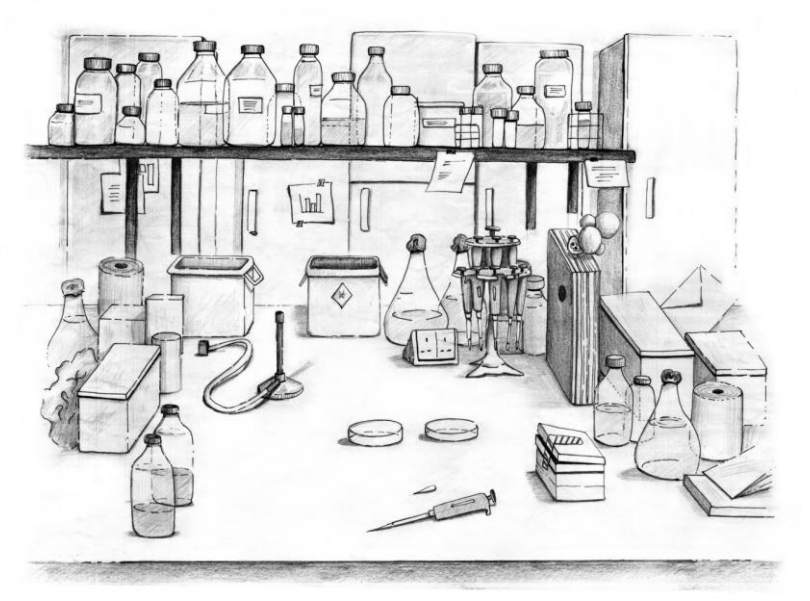

Figure 3. Composite diagram sketching working area.

Figure 4. Photographic study of the hand choreographies involved in pouring agar into a plate

4. Conclusions

More than a prescriptive framework for design, biomaterial probes are a suggestion than there are new ways of engaging living systems beyond remediation and substitution. In keeping with the lineage of derives, the methodology is intended to produce situations where prevalent assumptions and order can be questioned.

Engaging then with biological systems from a design perspective requires a form of engagement that challenges and upends instrumentality. The notion suggests not only a more thoughtful approach when integrating living systems in the process of design — it suggests an entirely different form of design. *Bacterial assemblages* suggests that designing with living systems involves engaging with a thick mesh of non-humans that go beyond the organism itself, and that extends to a number of encounters between the designer and materials, physical spaces, institutions and other researchers. The extended set of interactions involved in designing with living systems suggests that the boundary of the design space — the things a designer needs to engage with in working with living systems — expands exponentially. The living system, and the mesh constituted by the design assemblage, are hyperobjects, to borrow the phrase coined by Timothy Morton (2013).

Designing in a hypercomplex environment involves doing so without a clear idea of the outcome in advance. In this situation, there is a need for instruments that perform a cartographic function, in that they assist to navigate through an unknown design space. The bio-material probe performs this function. They constitute maps which are in constant change, drawing and redrawing their boundaries as the exploration progresses and providing a way of reading into an unreadable situation. At the same time, bio-material probes represent conversation starters — a way of developing a language to engage with non-humans.

Cognitive Ergonomics Components for Analysis of User Interface in Healthcare Industry

Mariia Zolotova*[a], Angela Giambattista[b]

[a]Xi'an Jiaotong-Liverpool University, [b]Sapienza University of Rome

*mariia.zolotova@xjtlu.edu.cn

Abstract | This paper shares a collaborative research in the field of User Experience and Design for Healthcare. In particular, it explores methods of Cognitive Ergonomics applied to analyze User Interfaces in healthcare industry. Specifically, the interest lies in analyzing cognitive aspects of interaction and the way it impacts user experience in terms of efficiency in perception and decision-making. Cognitive aspects of interaction were approached via the key components of Cognitive Ergonomics identified through a thorough literature review and composed in a canvas based on the sequence of mental processes occurring during cognitive interaction. The analysis of the User Interface described in this paper represents one of the tests made to check the validity and the potential of the proposed method. The paper concludes with a discussion on how the method contributes to designing affordances and on possible future developments and design in healthcare industry.

KEYWORDS | HEALTHCARE, COGNITIVE ERGONOMICS, ANALYSIS, INTERACTION, USER INTERFACE

1. Introduction

The research has started from an observation that designers should consider more and more often cognitive side of interaction due to an increased complexity in design projects they are working on, that include social, economic, and cultural contexts, affordances, technologies, etc. Therefore, there is a growing need in tools that would support designers in such scenarios. Literature and methods of Cognitive Ergonomics provide the necessary expertise to propose such a tool for an analysis of complex cognitive tasks (Endsley, 1995). In parallel, the Healthcare sector was chosen as a context of application of such methods, as the complexity of user experience and interaction is notably high while the need in new designs is rising. This observation has gained significance after conducting a User Research at a hospital in a Neonatal Intensive Care Unit, where babies born premature receive their first care. It was noticed, that doctors have to perform their job in a context that seems to be far away from 'ergonomic': multiple screens, tubes and other elements located in a manner that neither support naturality of gestures nor the ease of interpretation of the information. Medical equipment at Intensive Care units is characterized by a high quantity of symbols and signals, both visual and audio, and each of these symbols are crucial for patient safety. The reason for conducting a research on Cognitive Ergonomics and integrating its methods into industrial design practice was to provide such a tool that would guide designers in these complex contexts and to ensure that their designs satisfy the needs of their users (e.g. doctors and patients). After a thorough research on Cognitive Ergonomics, a set of Cognitive Ergonomics components was proposed (Zolotova, 2019) with a hypothesis that these components can constructively contribute to designing cognitive aspects of interaction by systemizing the analytical part of the design process and, thus, helping to achieve a cognitively ergonomic solution. The components and the hypothesis will be described in the paragraph 'Methods'.

A parallel part of this research work was specifically dedicated to observing the developments in the healthcare sector, highlighting the tendencies in user behaviors and design opportunities. The outcome of this research phase was the identification of four trends in the future healthcare (AA.VV., 2014, Tsekleves & Cooper, 2017, Giambattista, 2017). These trends cover patients' ability to make independent decisions related to their health, new ways of delivering healthcare, and novel technological achievements that improve medical tools. A more detailed description of the trends will be provided in the paragraph 'Context'. Paragraph 'Results' will describe an example of analysis conducted using the method of Cognitive Ergonomics Components. The method was applied to evaluate the efficiency of user's perception and decision-making in interaction with the design of a User Interface of a Neonatal Transport Incubator. The paper concludes with a discussion on possible contribution of this method to designing for the healthcare industry.

2. Context: Trends in Healthcare

Traditionally medical equipment was seen as a tool for delivering acute care but, due to various influences, the medical equipment now also includes psychological aspects. In recent decades, the concept of health is shifting from the idea of 'absence of disease' towards physiological and mental equilibrium and wellbeing (Huber et al., 2011). Moreover, as the healthcare industry develops, the more definitions appear to satisfy the needs of each particular scenario or context (Leonardi, 2018).

The future potential of design for health can be explored, for example, through the prism of traditional design disciplines such as architecture, communication, product, service, and interaction, while covering key areas of health, such as acute, chronic health and aging are good for the public (Tsekleves & Cooper, 2017). Theses authors have applied coding to the analysis of data and came up with a list of challenges, opportunities and new design trends in healthcare. According to their research, the trends are self-management healthcare, person-centric healthcare, holistic healthcare, community healthcare, health-promoting/preventative care.

Parallel to that, PSFK, a company that applies research to study user behaviors in various markets, has published a report on 'Future Health' (AA.VV., 2014) outlining four trends in health-related products, such as Behavioral Nudge, Empowered Patient, Orchestrated Care, and Augmented Treatment. By studying these two groups of trends and tendencies, it was possible to notice similarities between them. Particularly, both 'health-promoting/preventive care' and Behavioral Nudge speak for a need in products/services that would shift people's behavior towards a healthier lifestyle; 'self-management healthcare' and Empowered Patient speak about people being more informed and able to make decisions related to their health, and Orchestrated Care and 'community healthcare' describe products/services able to deliver new models of care. Eventually, Augmented Treatment intends with 'augmented' the new technologies that improve medical tools. In total, each trend provides the user with certain objectives and goals to pursue and proposes new user scenarios that would require new behaviors and learning to interact with new products and services.

Behavioral Nudge

'Nudge' is a concept in behavioral science, which uses indirect suggestions as ways to influence the behavior and decision making of groups or individuals (Wilk, 1999). The need

in ‘nudge’ lies in the fact that people tend to act against their interests (Koster & Van Der Heijden, 2015), and therefore nudging techniques aim at people making decisions to their advantage (Parkinson et al., 2014). At the PSFK, they have noticed a growing need of people in acting in a self-beneficial way, which would lead to a growing number of products satisfying this need. In the field of healthcare, self-beneficial behavior is considered the one that leads to both mental and physical health in the long term, which would therefore possibly exclude the acute care and would call for preventive methods. Tsekleves and Cooper (2017) also mentioned a trend in health-promoting/preventative care. Regarding Product Design, for Behavioral Nudge, reference is made to those tangible and intangible artifacts which call users to consciously manage their care, both in the prevention and management phases. Such devices tend to favor the characteristics that involve users’ emotions: embracing a holistic approach to a problem, such devices offer solutions that are functional but at the same time pleasant (Foqué & Lammineur, 1995).

Empowered Patient

Empowerment is defined as “a process through which people gain greater control over decisions and actions affecting their health” (Kickbusch & Nutbeam, 1998). The WHO defines patient empowerment as a process where patients understand their role, possess the knowledge and skills from their health-care provider to perform certain tasks in an environment that recognizes cultural differences and encourages patient participation. This is possible due to the use of technologies that facilitate access to information, such as the Internet, peer-to-peer sharing, health devices, etc. However, having ‘power’ is also a responsibility, that not every patient is ready to take. The phenomenon also includes the questions of patient’s safety. The products for Home Care have undergone a sudden increase both in terms of numbers and technical complexity (Tosi et al., 2016). Some of these medical devices are introduced on the market as consumer products that allow users to manage their health care in a more convenient and independent (also economically) way. The migration from hospitals to home is due to the increase in costs of healthcare, the lack of suitable facilities and qualified personnel (Chamberlain, 2015). As a result, the range and complexity of medical devices used outside of formal health institutions are on the rise. The risks associated with the malfunctioning and/or failure or incorrect understanding of the methods of use of the interface, of the control and adjustment elements, of the assembly/activation sequences, etc. intensify (Tosi & Rinaldi, 2015). This trend raises questions on how designers can ensure that the product is used exactly in the way it was supposed to be used.

Orchestrated Care

The scenario of this trend describes the products linked to the world of the Cloud, that use wearable and mobile technologies able to trace in a holistic way the people’s lifestyle. The healthcare sector receives more live data from apps and devices, and medical decisions will be likely made not according to the patient’s ‘feelings’ that might be wrongly interpreted but

based on real data, however, the issue will be to read it correctly. According to PSFK (AA.VV 2014), care will be delivered based on the preferences of the patient, and the relationship with the physician will become more virtual. The pervasiveness of the technological connection, the connectivity of technological supplies, the ever-increasing bio-compatibility of interfaces, these are the trends allowing delivering personalized care. Examples are all the design experiments that exploit the Internet of Things (IoT) technologies for continuous tracking and dialogue with healthcare facilities and practitioners. The design focus here is to identify user needs to provide the personalized care (Chaudhuri & Lillrank, 2013). The tools allowing to conduct deep user research will be welcomed, as they would serve as a base for creating new niches in the market of the healthcare sector.

Augmented Treatment

This trend includes high-performance technological tools, such as those for visualization using Augmented Reality and Virtual Reality, 3D printing techniques for creating implants and prostheses, and also everything related to Assistive Technology. AR/VR in the medical field is used for the surgical training, planning of operations, for open surgery sessions, endoscopy, and radio-surgery (Riva, 2002). Product designers usually prefer to work with 3D printing, exploring the properties of the materials to design prostheses and braces, as it allows adjusting them to the patient's needs, offering substantial benefits on waiting times and costs. It also opens opportunities for bottom-up solutions within Do-It-Yourself logic. The concept of parametrization and geo-localized production opens a way to new scenarios for the design of social innovation. To sum up, scientists, engineers, designers, makers are exploring the opportunities provided by the new technologies to either improve the existing medical tools or to solve economic issues related to healthcare. IT together with 3D printing technologies empower people to apply their knowledge and competence to solve the problems that otherwise would have remained ignored or inaccessible.

3. Methods: Cognitive Ergonomics Components

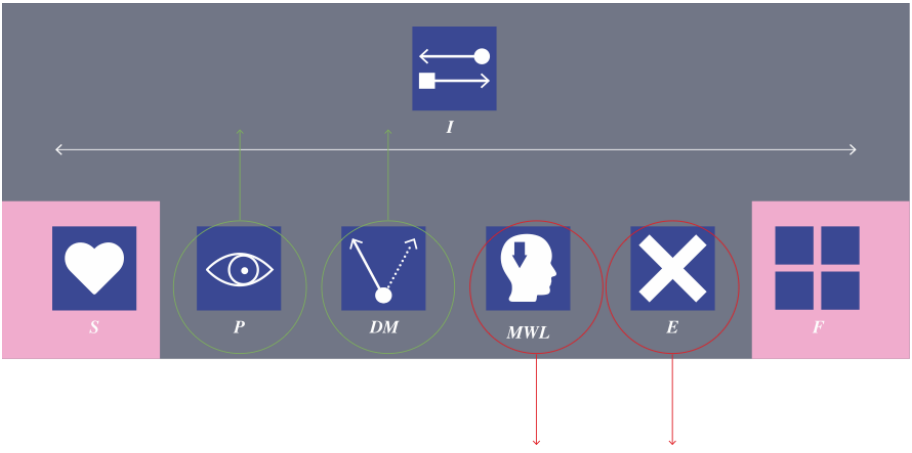

Figure 1. Cognitive Ergonomics Components: Interaction (I), Subjectivity (S), Functionality (F), Perception (P), Decision-Making (DM), Mental Workload (MWL), Error (E). The scheme represents a balanced interaction where P and DM are high and MWL and E are low.

Cognitive Ergonomics was chosen as an approach to cognitive aspects of interaction in its complexity. The aim was to find a way in which it could provide a valuable contribution for industrial designers to analyze and design complex cognitive interactions.

The research findings are Cognitive Ergonomics components composed to describe sequence of cognitive interaction (Figure 1) (Zolotova, 2019. In this paragraph, brief extracts of the theoretical grounding will be provided that would explain the methods applied to the analysis of best practices in Design for Healthcare.

Cognitive Ergonomics has three concepts that are considered of importance in this research: Distributed Cognition (DCog), Activity-System, and Situational Awareness (SA). DCog sees cognitive processes as a result of relationships between internal mental representations and the external environment (Hazlehurst, Gorman & McMullen, 2008, Hutchins, 1995). Meaning that people's cognition is not only contained in the head but distributed in the environment. Activity-System is a minimal unit of analysis of human actions where an activity means the engagement of individuals towards a certain objective (Engeström, 1987). Meaning, that every interaction is significantly defined by its goal. SA describes how people perceive and comprehend elements in the environment and how they project them to the near future (Endsley, 1995, 2017, Endsley & Garland, 2000). These three concepts have framed the understanding of cognitive interaction processes, describing where it occurs

(DCog), what is the reason for individuals to engage in interaction (Activity System), and how people perceive the environment and act in it (SA).

Two books gave key insights that eventually led to proposing the set of Cognitive Ergonomics components: "Ergonomics, project, product" (Tosi, 2005) and "Cognitive Ergonomics" (Di Nocera, 2011). Di Nocera focuses his attention on such concepts as interface, error, mental workload, automation, decision-making, situation awareness, usability, etc. While F. Tosi names the following components of Ergonomics: 'physical' ergonomics, 'User-Centered Design'(user needs), and 'New Human Factors' (emotions and other 'subjective' user needs). Further reading on these concepts has eventually led to the definitive set of the 'components'. Specifically, a big contribution gave the scheme of Situation Awareness introduced by M. Endsley, who is one of the major authors in Cognitive Ergonomics (Figure 2).

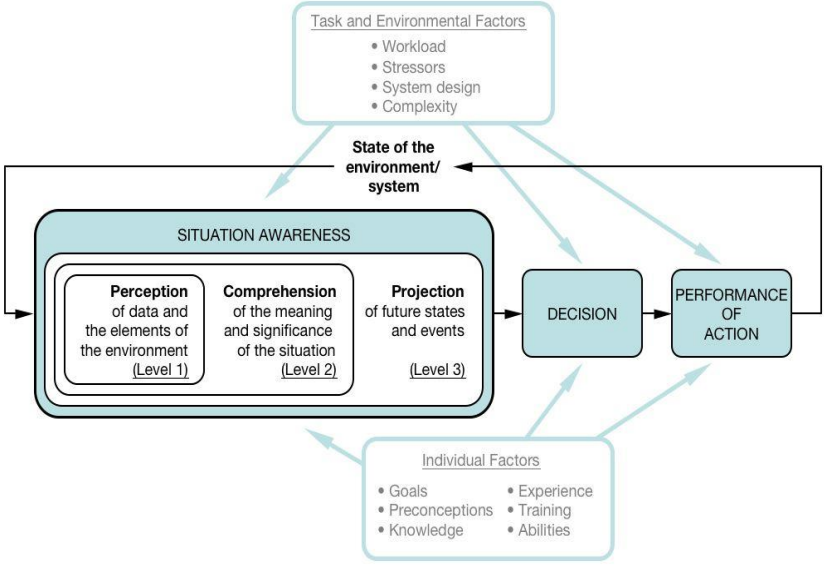

Figure 2. Situation Awareness model. Endsley's model of SA. This is a synthesis of versions she has given in several sources, notably Endsley (1995) and Endsley et al (2000).
Source: Public Domain, https://en.wikipedia.org/w/index.php?curid=11319693

The identified components are subjectivity, functionality, perception, decision-making, mental workload, error, interaction. Figure 1 shows how the components are interconnected. Each of the components has its definition and its location on the scheme, based on the relevant books and articles in the field and mentioned above. Below, there is a summary of each component's definitions.

'Subjectivity' (S) describes the user, the 'persona' (Cooper, 1999), his/her objectives and desires. Subjectivity is the starting point of analysis and it describes the goal of interaction. Just as the Human-Centered Design approach (Norman, 2013) places a person at the center of the design process, this model is based on the same principle and starts from the needs and desires of people. Taking into consideration the Activity-System model (Vygotsky, 1980), the analyzed person has to be associated with his/her goal in this interaction in order to frame clearly the analysis.

'Functionality' (F) describes the environment where interaction takes place, the products/elements, signifiers (Norman, 2008), functions involved in interaction that are significant for achieving the goal. 'Functionality' refers to both actual functions and those perceived by a person (Gibson, 1966). 'Functionality' includes issues related to the compatibility between the physical characteristics of users and the constraints imposed by the context in which they operate (Tosi, 2005). Therefore, the term 'functionality' describes all the elements/products, both physical and perceived, that serve to achieve the goal set by the user as well as the environment in which s/he operates.

'Perception' (P) is the first among mental processes to be analyzed (Endsley, 1995, Endsley & Garland, 2000). Perception is the interpretation of incoming sensory information and is activated through vision, touch, smell, taste, sound (Schacter, 2011). Both physiological and psychological stimuli are taken into consideration for the analysis. The key for the understanding of 'perception' lays in Gestalt psychology that sees an object as a whole, through 'patterns' and 'configurations', rather than its components. The knowledge possessed by the user influences the way people perceive and interpret the incoming information (Goodwin, 1994). In total, the component 'perception' describes the process of sensory and cognitive perception and interpretation of the elements involved in the interaction.

'Decision-making' (DM) describes the moment of choosing among alternatives (Patel, Kaufman & Arocha, 2002), an action. It is the second of the mental processes to be analyzed according to the adopted Endsley's (1995, Endsley & Garland, 2000) scheme. A decision made by the user inevitably results in his/her action, and it was therefore decided to unite the decision-making process with the eventual actions since only actions are visible to the observer without any specific equipment and thus, countable. In this research, the idea of Kahneman and Tversky (1974) of 'heuristics of judgments' is adopted which implies that people tend to make decisions based on the available knowledge and similar examples in their memory.

'Mental Workload' (MWL) is the mental work perceived by the user, it serves to describe the moments of a poor performance of an operator, it includes moments of stress and of long-focused attention (Parasuraman, 1998). 'Mental workload' affects all the other mental processes in an either effective or ineffective way (Di Nocera & Pasquali, 2011). The division in 'effective' and 'ineffective' mental workload serves to evaluate the quality of the overall interaction process.

'Error' (E) describes actions that mismatch the goal of interaction and/or an ill-suited result. Avoiding human error is especially important in healthcare (Carayon, Xie & Kianfar, 2014). There is a tendency to work on error tolerance since it is assumed that error is a part of human nature (Patel et al., 2011): to include a possibility of error in the interaction could decrease psychological pressure on the user. In this research, 'errors' are understood as errors in action (by the user), in perception, communication, and selection (Di Nocera 2011). Accepted methods to observe and identify errors are: naturalistic (observation and noticing errors made in a natural way – slips and lapses) and questionnaires.

'Interaction'. Cognitive Ergonomics studies the interaction between human and complex technological systems with an aim to avoid failures (Ferlazzo, 2005). However, in the design field, interaction is rather seen as User Experience (Norman, 2005) that includes psychological, emotional aspects of interaction. 'Interaction' (I) stands for both physical and cognitive interaction occurring between the user and the product/system and includes all the above-mentioned components in it.

Figure 1 represents a scheme of how the components could be unified into a formula that would work for the designers. It describes interaction (I) between human (S) and an environment (F) through 'perception' (P), 'decision-making' (DM), 'mental workload' (MWL), and 'error' (E). The low ability to perceive (P) would negatively impact the ability to make decisions (DM), that would in its turn contribute to the rise of 'mental workload' (MWL) and, eventually, to the quantity of 'errors' (E) (Figure 1). The steps that a designer should take to perform an analysis of interaction by following the scheme are:

- to describe the 'subjectivity', i.e., the user and his/her objective.

- to identify the 'functionality', i.e., all the necessary elements needed to reach this objective.

- to evaluate the user's ability to perceive and make decisions while comparing it to the level of mental workload and the occurrence of errors. The main idea of this analysis is to find the misbalance within the interaction process.

A 'correct' interaction is, therefore, the one that allows users to reach their objective in an effective, efficient, and satisfactory way, while an 'incorrect' interaction would result in actions/effects deviating from the initial objective and result in stress.

The proposed scheme sees this set of 'Cognitive Ergonomics components' as a useful tool for designers to design complex interactions because it systemizes the analysis of interaction

through the components and helps designers synthesize all the inputs related to the interaction process in a structured way.

4. Results: Designing User Interface of a Neonatal Transport Incubator

This paragraph tells the experience of analysis of a User Interface from the point of view of a user, applying the set of Cognitive Ergonomics Components as a tool to identify errors in interaction and therefore in design.

This research project was developed in collaboration with an Italian manufacturer of neonatal medical equipment, which allowed performing a test of the components applied to designing User Interface. Interface is becoming the key focus of research for Cognitive Ergonomics [Bagnara & Pozzi, 2011]. The purpose of this test was to verify if the proposed set of components is useful for the analysis and re-design of an already existing product – a digital interface of a neonatal transport incubator (Figure 3).

Figure 3. Neonatal Transport Incubator by Ginevri SRl.

This medical equipment ensures stable environmental conditions, such as temperature and humidity, for the neonate in a context of its transportation, normally, between the hospitals. The criterium of a successful result was the improved user interaction with the incubator in terms of its efficiency and usability. The incubator, shown on Fig.3 is under development and is preparing to be launched at market. The key problem of this device was in lack of usability due to complexity of operations possible to perform with this device and due to 'engineering-based' design. The original User Interface design was based on the engineering requirements, responding to the technical needs, while the user component was missing. This was a good case-study for analyzing errors in design and interaction.

The company provided access to this device for this research project in order to identify where the interaction design problems are. The testing was done without the neonate for safety reasons. Together with the engineers of this device, the author has performed interaction with the incubator. Following, the canvas structure, the experiment started with setting the goal, and the engineer has suggested possible results, e.g. "to set the parameters for temperature". Pursuing this goal, the author tried to identify possible actions based on previous observations of doctors' actions with the similar devices at a NICU (Neonatal Intensive Care Unit) and according to the graphic interface of the incubator. During these trials and following the structure of the canvas, the author has identified the sources of errors in design: misleading symbols, confusion in hierarchy and logics.

Applying the scheme of Cognitive Ergonomics Components, the analysis of the incubator's User Interface can be described as follows (Figure 4). Below is the description of one step perception/decision-making:

'Subjectivity' (S): the user is a healthcare professional, Dr/Nurse; user's general goal of interaction is to maintain the baby's temperature, whilst a specific objective (to test) is to set the parameters for the temperature.

'Functionality' (F): transport incubator, touch screen; simulation of a real-life environment.

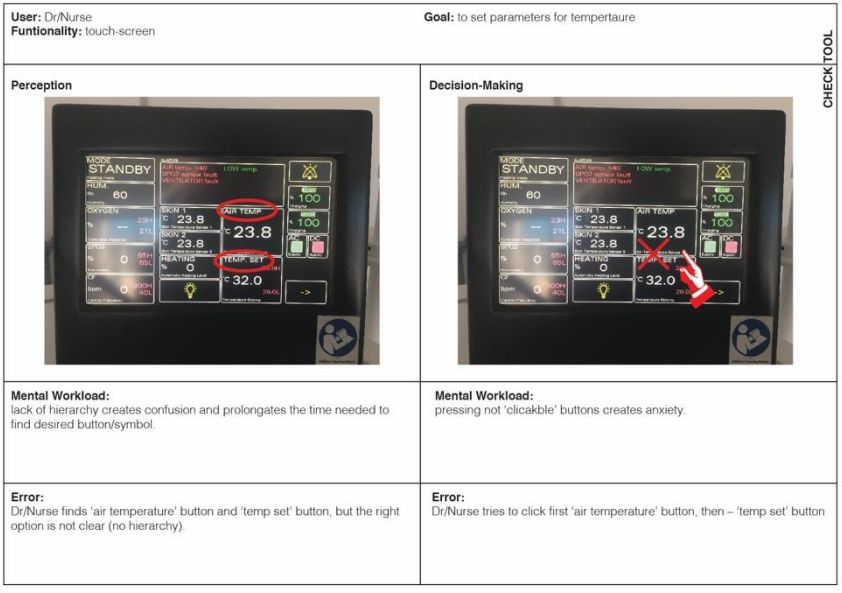

Figure 4. Analysis of User Interface of a Neonatal Transport Incubator (example

Analysis of 'Perception' (P):

'Perception' (P)	Senses involved are sight and touch; perceived elements are buttons, colors and texts of the digital interface (touch-screen); process description: Dr/Nurse is looking at the touch-screen for a button/indicator of Temperature (Figure 4).
'Mental Workload' (MWL)	Here the quantity of information to elaborate by the user is being analyzed: lack of hierarchy creates confusion and prolongates the time needed to find desired button/symbol.
'Error' (E)	Here mistakes related to perception are being observed: Dr/Nurse finds 'air temperature' button and 'temp set' button, but the right option is not clear (no hierarchy).

Analysis of 'Decision-Making' (DM):

'Decision-Making' (DM)	Mental actions are: interpreting numbers/texts from digital interface; manual actions are: pressing buttons on touch-screen.

	Process description: Dr/Nurse tries to click first 'air temperature' button, then – 'temp set' button
'Mental Workload' (MWL)	In reality the buttons are not 'clickable', pressing them several times trying to make them work creates anxiety.
'Error' (E)	None of the options ('air temp' / 'temp set') was correct – User Interface was totally misleading, external consultation needed to identify the right button for setting temperature.

This analysis allowed identifying and summarizing current problems in User Interface design. In a similar manner, a new design can be subject to analysis.

5. Discussion and Conclusions

The test described in paragraph 4 'Results' has served as an example on how Cognitive Ergonomics Components can be applied to the analysis of a User Interface. The analysis was quite detailed and laborious, and therefore is more adequate for scenarios of highly technological interaction characterized by informational overload on the user, such as a User Interface of a Neonatal Transport Incubator and other similar interfaces. The division of interaction into small steps (Task Analysis) allows conducting a thorough analysis whilst Cognitive Ergonomics Components indicate where to search for the problems in design based on user's actions and feedback. Such a tool could serve also as a report format provided by designers to their client, where all the steps, tests and improvements are fixed. Could this be a useful tool for the trends in Future Health? This tool for analysis (Cognitive Ergonomics Components) pays a lot of attention to affordances (Gibson, 1966, Norman, 2008) in design. Perception analysis is mainly based on the efficiency of the affordances and the evidence of failures in design is provided based on user's either correct or incorrect actions. Therefore, this analysis allows collecting data of examples of efficient and non-efficient symbols and other design-elements that are important affordances for a satisfactory interaction. This database could be seen as a collection of best-practices and mistakes in design to be implemented or avoided in designing future innovative healthcare products where users will need to confront with the unknown interactions.
Paragraph 2 "Context: Trends in Healthcare" describes the four trends in future health: Behavioral Nudge, Orchestrated Care, Empowered patient and Augmented Treatment. Behavioral Nudge aims at supporting user behaviors through delicate suggestions and indications. These could be APP notifications, color codes, specific shapes based on ergonomics or archetypes and other incentives and affordances. Testing the correctness of their perception by users would be useful to ensure the efficiency of the new designs: do these shapes and elements nudge users in the right direction? Orchestrated Care provides services via cloud interconnections, which implies designing clear hierarchy and intuitive User Interfaces that allow users navigate through complex healthcare data. Analyzing users'

perception of such systems would allow identifying the most optimal path for achieving their goals. Empowered Patient trend suggests that users will always need to be more and more informed and have power over their health. However, this implies risks in making harmful decisions if made uninformed or based on emotions. There is an ongoing discussion (Kleinpeter, 2017, Chiruvella & Gudatti, 2021) on ethical implications of exposing medical data to patients: to which extent the patient can be informed? Ergonomics and Human Factors (Carayon, 2014) is often employed in Healthcare with a purpose to ensure patient's safety. Thus, integrating Cognitive Ergonomics Components at a User Research phase in design would provide more guaranties that patient safety is thoroughly considered. Observing users' perception of medical data and their reaction to it could allow identifying aspects that provoke an intense emotional reaction and therefore harmful for patient's psychological health and avoiding them in design. Augmented Treatment trend describes medical tools based on newest technologies, such as using rapid manufacturing to produce prosthesis and other elements of care, VR/AR technologies to simulate various scenarios or to create a distracting ambience for children, etc (see examples in Paragraph 2). Applying Cognitive Ergonomics could be beneficial for designing such ambiences, because users would need to feel safe and confident while exploring a new territory. Designing elements that would guide users to interact efficiently with such ambiences would help designers satisfying users' needs.

The limitation of this canvas is that designers would still need to be trained to perform Task Analysis and have enough of design expertise to identify quickly and precisely the affordances and the actions they provoke. Possibly, to achieve more precision, designers could be assisted with available technologies typically used by the ergonomists, e.g. an eye-tracker. On the other hand, the fact that this analysis can be still performed without any equipment and based only on the designer's expertise, makes this tool accessible for any designer in need.

Connect art and science for a functional biomimicry in design

Andrea Forges Davanzati

Abstract | Nature provides a immense variety of visible and invisible forms trying to hide from our eye, strange and mysterious, in continuous movement and evolution.
Many contemporary artists have been inspired by nature forms, mostly after the invention of the microscope which revealed endless worlds, extra small and definitely evocative for form and colour: diatoms, ciliated, protozoa and mold, paramecium and radiolaria.. Microorganism, in addition to having a strong scientific interest, have become source of inspiration for multicolor patterns and sophisticated stuctures. These forms, normally invisible, have been discovered and analyzed, have been approached, multiplied, magnified, overturned and hooked on other elements of the modern visual language in such a way that they lose their original concept to become a abstract work of art.

KEYWORDS | ONE, TWO, THREE, FOUR, FIVE

1. Science and art: today

1.1 The American biomimicry

Even if the discipline of biomimicry is still little known in Italy, in the rest of the world in a powerful word, associated to an unceasing blossom of new applications and professions, a real core of a new cultural knowledge, therefore also of power, which stimulates the growth of a new market and a new managerial specialization.

A brief history: during the first half of the twentieth century, a small group of American scientists thought of applying physics to the study of biological functions in a multidisciplinary way, this led to the definition of a new discipline that they called biophysics.

In 1957, Otto Herbert Shmitt, American scholar and inventor, at the height of his studies on nerve endings and bioelectric interactions, first used the term biomimetics, from the Greek bios: life, and mimesis: to imitate, to better define the new field of Research. (1)

Shmitt was part of a generation of scientists eager to get out of the narrow confines of their specific disciplines to embrace a new interdisciplinary way of studying and research that included different scientists and especially different groups of specialized technicians.

In 1958 another American scholar, belonging to the military, Jack Steele, used the term Bionica for the first time to define the science of systems (processes), having functions copied from nature, or having similar characteristics. (2)

Today biomimicry is a multidisciplinary approach in constant growth, active in the most important academic sectors such as science, technology, engineering and mathematics. This exponential development of study has created the exclusive Biomimicry institute in Montana, Janine Benyus has theorized the ten laws of Biomimicry, other research centers have been formed in America and in the world, in university and industrial centers. In England in 2013 the study of biomimicry was introduced as a subject of technology and design study for children aged 11 to 14, in the rest of the world the application study of this matter remains reserved for specialist studies of engineering and architecture. From this brief historical mirror, the specific interest that this theme arouses for possible investment developments in industrial research is evident.

A few examples, to start with: the velcro, invented, but it is better to say patented in 1955 by a Swiss engineer, derives from the study of a seed of the lapola plant, very common, covered with tiny hooks that make it annoyingly capable of sticking to the hair and fabrics that naturally allow it to reproduce in distant places and thus favor a territorial diffusion. Today the velcro, produced in different plastic types, has become common in any object that needs an adjustable temporary locking system. It also represents the safest and longest coupling used in aerospace engineering.

Likewise, from the study of the water-repellent properties of the lotus plant (the leaves) it was possible to derive a paint or a treatment that repels water from surfaces and fabrics, together creating a self-cleaning coating; from the shapes of the seeds at the mercy of the wind new formal schemes for efficient and revolutionary wind turbines, from the structures of the termite mounds and anthills new systems for efficient and extremely low energy consumption air conditioning. The study of natural form and function (other example from the gecko's paw = a new substance or super adhesive structure) now also includes the study of principles (the social structure of bees as a specialized social model to be applied in the company). The examples are now many and develop in numerous application fields, but let's go back to look at the historical development of the research process in general terms.

1.2 Meanwhile in Europe:

As I introduced, while in America the words corresponding to this natural study were invented, signed and patented, in the Central European cultural cradle of Freud and Piaget, as a natural continuation of C. Darwin's naturalistic studies in the late nineteenth century, the study of nature took directions less strained towards profit and immediate industrial application and more focused on pure research. In 1948 Karl von Frisch published in Germany: "Animal architecture. The scholar's attention is mainly focused on the analysis of the construction structures of different animal species, in particular the world of arthropods, insects, because with just under a million species it represents the most numerous and varied in absolute; just think in relation to the entire list of mammal species that only counts a few hundred. Immediately following, Konrad Lorenz's study lays the foundations for understanding animal behavior, thus founding modern ethology.

1.3 Bioapplication: wright or wrong?

This is to better outline the global historical landscape responsible for creating the foundations of natural and naturalistic research. Beyond the immediately positive and praiseworthy aspects regarding the study of natural elements or processes aimed at improving our life, it is also necessary to underline the possible risks that this passage competes in a global vision. I have already mentioned how the search for new products derived from natural examples is actually dictated by a profit logic, but the real risk is represented by the fact that this could lead the relationship between natural and artificial towards a substantial modification. On the one hand, in fact, the new biomimetic sector could modify the artificial to make it more efficient and morally acceptable, on the other the artificial could have the power to modify the natural. An example is the biocapitalist landscape in which, due to the need for greenery, the forestry industry creates new forms of nature based on industrial requests, trees become elements of a production process thanks to genetic modifications aimed at speeding up the growth and efficiency of the production. Biocapitalism offers great possibilities (just think of the creation of green species capable of purifying the atmosphere, but it represents serious risks for the ecosystem and especially for bioversity. (Can a homogeneous, controlled, serial nature be considered natural according to

the needs of the human being alone?). This reflection is worryingly reflected in any breeding or cultivation, but also, more generally, to the assumption of the term "natural" with the implication of an increase in market value. I am reminded of the example of the apple sold in the stalls of any supermarket in New York, we go from the normal apple without any further wording, so we can suppose that it is controlled, genetically modified to resist pests, frost or weather resistance, perfect in shape and color, but almost artificial, to the slightly more expensive "biological" apple, then to rise in price for the "organic" apple and finally to the "amish" apple, expensive because it is not perfect, sometimes misshapen and often buggy, expensive as it totally "natural".

It is curious to think that the use of pesticides and fertilizing elements still implies a production surcharge that small farmers cannot sustain. The formal camouflage of the natural world could be attributed, even in modern architecture, to a criticism that had already arisen in the analysis of some organic forms that have now become real stylistic features of an expanding current. Without diminishing the importance of bio-inspiration in many buildings, conceptually we can see the ever closer link between ecology and economy, in a new definition that Rhem Koolhas defines Ecolomia. In his text, Junk Space, Koolhas theorises "oxygen banks, chlorophyll fort knox, eco reserves such as blank checks to obtain further pollution" and also "stations unfold like steel butterflies, airports sparkle like cyclopean dew drops , bridges join shores often overlooked as grotesquely enlarged versions of a harp, with each stream its Calatrava "(3) This vision is pessimistic and negative, however the study of the natural world aimed at new organic structures and the general attention for the bio-inspired method can however open new horizons. Not only forms, but processes and systems can in fact be inspired by nature, and it is in this direction that the greatest results can be obtained.

1.4 Science and art, art and science

In parallel with the formation of the applicative and functional study of nature, the cultural movement Art and Science has developed since the early 1980s, aimed at uniting the two worlds often kept separate from institutions and by a part of scholars who are wary of scientists. art understood by them as chaotic and unruly. In reality, the interdisciplinary research of Art and Science has historical roots in the Renaissance and has always been the bearer of excellent examples. Nature has always been celebrated and analyzed to reveal its hidden laws capable of inspiring and justifying the new canons of beauty and perfection, and science has been the suitable means or instrument to transmit and apply it. A direct application of this research could for example positively transform the function and usability of the traditional museum, in crisis due to the low turnout of the public who increasingly prefer a more dynamic vision, videos, or multimedia or multi-sensorial experiences. Overseas, the American museum has been able to modernize by inserting sets, projections, objects and direct applications in games, manipulations and multimedia experiences in structures previously exclusively dedicated to collections. The public generally cannot stand the still collections of animals or natural species kept behind the glass. The artistic creation,

intended as a formal search for celebration of nature, inserted in a museum context, could find the real consideration in the plants or animals on display, so as to make the point of origin and belonging of the research legible, at the same time inviting the viewer to imagine other applications and variations possible. In this way the municipal museum centers such as aquariums, natural, scientific and anthropological could expand their themes and their didactic panorama.

Science applications in the rapid progress of interactive systems and modern media need art, through which they can in fact aspire to be a little more lasting, absorbing a part of eternity to which art tends. Art, for its part, in its most current sense, including all its forms, with installations, videos, its many conceptual applications, needs science to rejuvenate itself, renew itself, communicate and transmit, and bridge the gap cultural that otherwise relegates it to an elitist environment.

Another interesting development of the relationship between Art and Science can be found in the structure of Arte Sella, the only example in Italy of the largest international movement Art in Nature. Located near Trento, it unfolds as an outdoor exhibition museum, in a forest, and for many years has exhibited examples of natural works, often ephemeral, made exclusively with natural materials such as stones, branches and leaves, or simply earth brought back. You can observe real sculptures, but also Land Art architectures and applications, stimulating for creativity and remarkable for the rigorous respect for the ecosystem.

It represents a way of expressing refined artistic concepts through the construction of elaborate often geometric structures (tensile structures and concatenations of modules) derived from natural scientific study.

A modern Biomimesis, or Organic Design, or Nature Design Thinking should reunite and merge with Art and Science, where the main task of artistic research intended as a subtle search for pleasure is to provide an un-utilitarian vision of natural forms and functions, of pure celebration and praise of beings, in the vision of social progress certainly even less expensive in terms of energy and consumerism.

1.5 Organic Design Thinking

I also believe that in teaching disciplines as design thinking linked to natural study, with its current issues related to climate problems, species conservation and resource management, can also be directed towards a type of speculative research, pure, less focused on the frantic achievement of immediately applicable results and unique solutions.

The fuel of research is passion, this must gratify study in its perhaps most tedious and compiling moments; therefore also pleasure, fun and irony, upsetting and overturning the pre-established data and patterns.

Without a doubt, it is useful to consider the analyzed topic by changing perspective and perspective, or to change the points of view, also from a conceptual point of view.In this sense, the application of an artistic "system" helps to unleash creativity beyond the boundaries of utilitarian and finalized research.

I give an example. Recently some students (the formation of heterogeneous study groups is always advocated), have proposed the adhesive as a research theme, analyzing it towards the design of an innovative cellular glue; a very ambitious undertaking in itself since it requires a lot of data belonging to chemistry, anatomy, medicine and physics not easily available in a design study facility nor within the reach of a single student.

The theme is certainly very current, recently we have witnessed the spread of modern and innovative inventions in this sector, cyanoacrylates, silicones, various adhesives, reactants to catalysts, grape rays, white light, oxygen heat and so on. However, the general and speculative study of this topic could also include its conceptual meanings, linked for example to a perfume or a smell that adheres to it, or a nickname that remains stuck, or even the persistent memory, the repeated gesture and the follow one another and take root in the same pattern.

Spamming is adhesive. The irony and cultural deregulation like that of Bruno Munari who not only invents, as a designer, a chair completely distorting the ergonomic rules and creating a strongly inclined seat that makes it impossible to sit down, but even gives it the name of "chair for visits very short ", helps, stimulates and frees the boundaries of design thinking.

Development of a test setup for validating a cognitive assessment platform within ICU's

Muriel De Boeck*[a], Philippe Jorens[b], Guido De Bruyne[a], Kristof Vaes[a]

[a]University of Antwerp, Faculty of Design Sciences, Department of Product Development
[b]Antwerp University Hospital, Department of Critical Care Medicine
*muriel.deboeck@uantwerpen.be

Abstract | Medical care is one of the most important and urgent areas to obtain insights and better understanding of the workflow of the caregivers using a human-centred approach, particularly in departments where caregivers' activities are crucial to human lives, such as the intensive care unit (ICU). Within this paper, we used a combination of quantitative and qualitative approaches to investigate role stress on ICU-caregivers. The aim of this preliminary study is to develop a test setup as preparation towards the development and validation of an instrument to monitor cognitive states, namely a Cognitive Assessment Platform (CAP). This resulted in (1) a task analysis, which we translated into an app for easy task registration, (2) a selection of sensors to measure cognitive states at caregivers of an ICU and (3) a questionnaire based on the Stress Questionnaire for Health Professional (SQHP).

KEYWORDS | COGNITIVE STATE, PHYSIOLOGICAL MEASUREMENTS, WEARABLE SENSORS

1. Introduction

The basic principle of human-centred design is that products and services result from a thorough understanding of the physical, cognitive and emotional needs of users. This approach enhances effectiveness and efficiency, and improves human well-being (ISO, 2010). To understand human functioning in highly stressful and complex environments, a human-centred approach can provide a better comprehension of the needs of the different kinds of people who interact with each other in such an environment. Moreover, it counteracts possible adverse effects in human health, safety and performance (Van Zyl and De La Harpe, 2014).

Safety critical environments, such as medicine and healthcare, are very important and urgent areas to obtain insights and better understanding of the workflow of the staff using a human-centred approach. Particularly in departments where performed activities are crucial to human lives, such as the intensive care unit (ICU) (Ohmura et al., 2006). Adverse events, defined as injuries or complications that are provoked by a medical human error rather than the patient's underlying disease, occur in about one-third of cases in adult ICU patients and the risk of error is cumulative (Baker et al., 2004; Orgeas et al., 2008; Seynaeve et al., 2011; Molina et al., 2018). The risk factors of adverse events include high nursing workload, caregivers' sleep deprivation or fatigue, communication failure, a high patient-to-nurse ratio and poor management (Valentin et al., 2006; Bucknall and Tracey, 2010; Ksouri et al., 2010; Pagnamenta et al., 2012; Steyrer et al., 2013; Faisy et al., 2016). Cognitive limitations such as fatigue, mental workload, arousal or stress, may result in errors during task intensive activities and deteriorated performance.

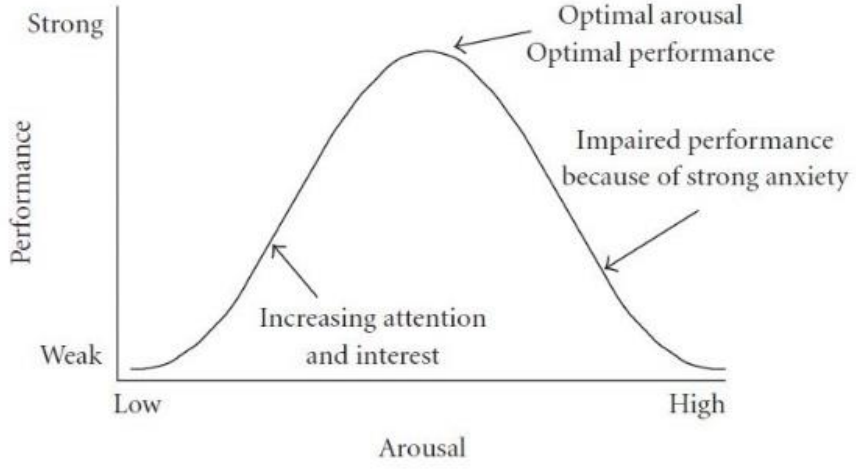

Figure 1. Illustration of the Yerkes-Dodson law (Dodson and Yerkes, 1908)

The principle which states that performance and the mental state of arousal or stress are directly related, was proposed by psychologists Yerkes and Dodson (Dodson and Yerkes, 1908). They indicated that behavioural performance increases with physiological or mental arousal, but only up to a certain point. This means that if the arousal-level is too high, people not only experience psychological discomfort such as stress and/or anxiety, but can no longer function optimally due to a reduced level of attention, memory and cognitive processes. In conclusion, the Yerkes-Dodson law (see Figure 1) is a well-cited century-old principle, which shows that the relationship between arousal and behavioural performance can be linear or curvilinear, depending on the difficulty of the task.

Physiological parameters allow monitoring of cognitive states such as stress or arousal by quantifying responses from the brain and nervous system, cardiovascular system and visual system. For example, heart rate variability (RR-interval) allow gaining insight in stress levels (McDonald and Soussou, 2011), while EEG's allow quantifying arousal levels through analysis of brain waves, see figure 2 (Berka *et al.*, 2007; Stikic *et al.*, 2014; Liu *et al.*, 2016; Webster *et al.*, 2017). Through wearable computing it is possible to monitor these physiological parameters in real-time. Additionally, wearable computing is rapidly becoming a major research direction due to new developments in smart technologies, which may hold promises for enhancing product intelligence. In conclusion, workload intensive tasks, smart technologies and interpersonal variations in cognitive capacities induce a need to better understand human cognition and adjust care products and interfaces accordingly.

Several review papers regarding wearable sensor-based system (Pantelopoulos and Bourbakis, 2010; Banaee, Ahmed and Loutfi, 2013; Lakudzode and Rajbhoj, 2016) provide inventories of the most commonly used physiological parameters for health monitoring in literature and are summarised in Table 1.

Table 1. Summarisation of the most commonly used biosensors used for health monitoring according to current literature.

Type of signal	**Type of sensor**	**Description of measured data**
Electrocardiogram (ECG)	Chest electrodes	Electrical activity of the heart
Blood pressure - systolic and diastolic (BP)	Arm cuff-based monitor	Refers to the force exerted by circulating blood on the walls of blood vessels
Body (skin) temperature	Temperature probe or skin patch	A measure of the body's ability to generate and get rid of heat
Respiration rate (RR)	Piezoelectric sensor band around chest	Number of movement indicative of inspiration and expiration per minute
Oxygen saturation (SpO_2)	Pulse oximeter on finger	Indicates the amount of oxygen that is being transported in the blood
Heart rate (HR)	Pulse oximeter on finger or skin electrodes	Frequency of the cardiac cycle

Photoplethysmogram - Skin conductivity (PPG)	Galvanic skin response sensor	Electrical conductance of the skin (activity of the sweat glands)
Blood glucose (BG)	Strip-based glucose meter	Measurement of the amount of glucose in blood
Electromyogram (EMG)	Skin electrodes	Electrical activity of the skeletal muscles
Electroencephalogram (EEG)	Scalp-placed electrodes	Measurement of brain activity
Body movements	Accelerometer	Measurement of acceleration in 3D spaces

The aim of this preliminary study is to develop a test setup as preparation towards the validation of an instrument, namely a Cognitive Assessment Platform (CAP), which consists of a set of sensors that allow synchronous data acquisition of the different physiological measurements. The caregivers will also be questioned to verify whether the subjective results match the objective measurements. In a follow-up study, the CAP will also enable identifying stressful situations that require excessive workload or may degrade performance, and allow a synchronisation between the physiological data of its wearer and specific care tasks. Ultimately, this research shall contribute to the development of a full operational CAP to gain fundamental insights in and a better understanding of the workflow of the caregivers, which in turn could provide rich opportunities for further examination and discovery. For this research, we closely cooperate with the ICU department at the Antwerp University Hospital (UZA). This precursory study is an initial exploration regarding different aspects of the follow-up study and consists following research activities:

1. A task analysis based on therapeutic intervention scoring system (TISS-28) and observations. We translated this task analysis into an app for easy task registration, which will enable linking the performed task with the physiological data of the caregiver;
2. A selection of sensors to measure cognitive states – fatigue, workload and stress – at caregivers of the ICU of UZA. This based on literature reviews and on observations on their current working conditions (required for ethical approval);
3. Lastly, a questionnaire, which will provide a general qualitative overview of stress and fatigue levels specifically within the ICU of UZA (required for ethical approval).

2. Method

2.1 Task analysis and app development

Within this study, we performed a task analysis to analyse main cognitive activities of the ICU-caregivers at UZA and to set up a task inventory, which was crucial for the development

of the app. In a later study, the caregivers will use the app as a system to register the tasks that they are performing at that moment. This way, we can synchronize the monitored physiological data with the performed tasks and explore possible continuities.

We conducted the task analysis based on observations within the ICU of UZA and on the Therapeutic Intervention Scoring System-28 (TISS-28). TISS-28 is a tool used to assign scores to patients according to severity of illness and is used as an indicator of nursing workload in ICU TISS-28 (Miranda, de Rijk and Schaufeli, 1996).

2.2 Selection of wearable sensors

A selection of wearable sensors to measure cognitive states at caregivers within the ICU of UZA was made based on current state-of-the art according to the literature (see table 1) and on observations regarding the conditions within the environment of the ICU. This selection of sensors will be used in a later follow-up study.

2.3 Questionnaire

The questionnaire was set up in consultation with head nurse and confirmed by head of the ICU at UZA and the ICU team. The aim of this questionnaire is to obtain qualitative insights in the stress and fatigue levels of caregivers and to capture the professional experiences of nurses in aspects related to occupational stress. Therefore, we used the six sources of occupational stress according to the Stress Questionnaire for Health Professionals (SQHP) (Gomes and Teixeira, 2016). These six sources that we took into account consider aspects related to work and family affairs (managing clients, relationships at work and home-work interface), aspects related to specific nursing tasks and the time available to achieve them (leading training activities and work overload) and also aspects related to career progression and salary. The questionnaire was set up using Qualtrics software since it provides an extensive variety of types of questions (other than multiple choice or open questions), and since it is possible to combine it with SPSS software for analysing the data.

3. Results

3.1 Task analysis and app development

The task analysis resulted in a task inventory of all key activities within the ICU of UZA. Additionally, all key activities were classified in thirteen main categories to make task registration easier for caregivers, which are shown in Table 2.

Table 2. Task inventory based on TISS-28 and on observations.

1. Register parameters ○ General registration (every two hours) ○ Record an ECG	2. Hygienic care ○ Body care (hair, brushing teeth, shaving, etc.) ○ Change bed ○ Corpse care	3. Medication ○ Prepare medication

	○ Intimate toilet ○ Ostomy care ○ Offer bed pan ○ Offer kidney dish ○ Wound care	○ Via Intravenous infusion ○ Via syringe ○ Orally
4. Respiratory care ○ Oral care ○ Clean endotracheal tube ○ Aspiration ○ Intubation ○ Install non-invasive ventilation	5. Administrative task ○ Receive briefing ○ Write patient report ○ Prescribe medication ○ Order material ○ Fill out the Electronic Patient Dossier (EPD) ○ Fill out score form ○ Meeting	6. Nutrition ○ Offer food ○ Offer a drink ○ Feed the patient
7. Communication and support ○ With patient ○ With visitors ○ With doctor ○ With external staff	8. Mobility patient ○ Install patient ○ Transport patient ○ Turn and position patient in bed ○ Move patient to another bed	9. Acute care ○ CPR ○ Intubation
10. Logistics ○ Collect medication ○ Collect equipment ○ Call technical service ○ Unload medication ○ Order material ○ Refill carts ○ Refill boxes ○ Clean devices	11. Technical skills ○ Insert probe ○ Assist doctor (place catheter, bronchoscopy, …) ○ Place Intravenous infusion ○ Take blood ○ Take samples ○ Continuous veno-venous hemofiltration (CVVH)	12. Breaks ○ Short break (toilet, coffee) ○ Dinner break
13. Other ○ Supervise student ○ Educate a colleague ○ Other: …		

Further, we translated the results of the task analysis into an app, which will enable easy task registration for the ICU-caregivers. The main interface of the app is shown in Figure 2.

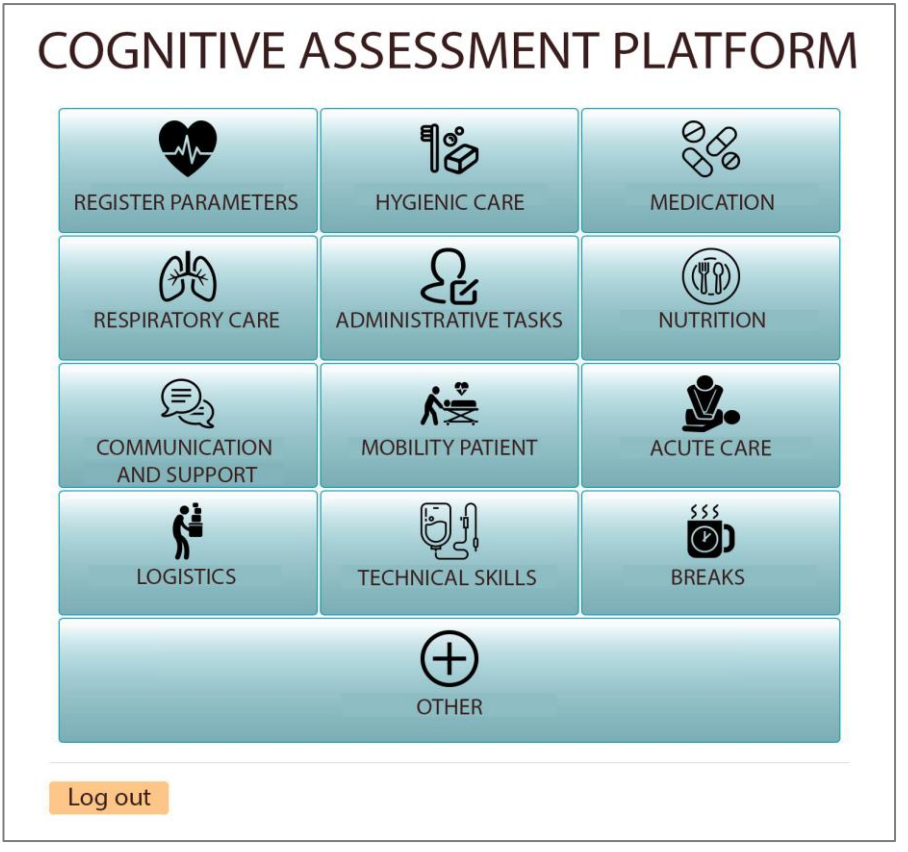

Figure 2. Illustration of the interface of the app, showing the thirteen categories of the tasks.

Every category has a list of tasks (see Figure 3a) that can be selected by the caregiver. By selecting a task, a timer starts recording the time (see Figure 3b) such that the monitored physiological data can be synchronised with the performed tasks and possible continuities can be explored (e.g. how does recovery occur, what is the importance of breaks, which tasks are most demanding, do the results correlate with the results of the questionnaire, etc.). Anytime, the user can go back to the previous page.

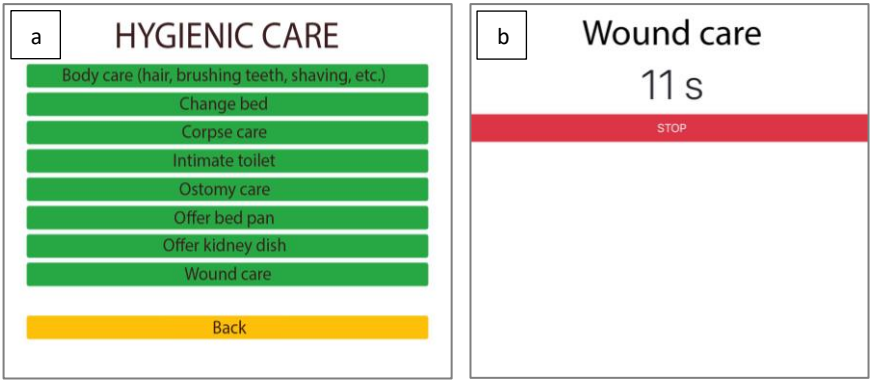

Figure 3. (a) Illustration of the interface after selecting a random category and (b) after selecting a specific task (in this case: "wound care").

3.2 Selection of wearable sensors

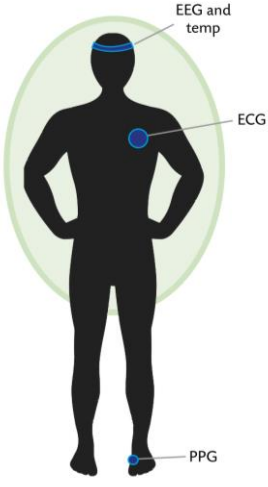

Figure 4. Placement of the selected sensors.

Based on field research, we encountered that the ICU-caregivers need to keep their hands and forearms sterile during their work, which means that we cannot place any sensors on these locations. Consequently, BP, HR and SpO2 could not be measured within this research (see Table 1). Further, body movements and EMG would not provide significant results within this context because of the caregivers' constant movement. BG would be too difficult to measure and RR would be too intrusive for the caregivers. Finally, these wearable sensors

and cables were attached unobtrusively to the body so that they would not interfere with the tasks of the caregiver. Considering the different sensors to measure cognitive state according to current literature, we selected ECG, skin temperature, PPG and EEG as shown in Figure 3. PPG is typically recorded non-invasively from the surface of the palms and fingers. However, the caregivers need to keep their wrists sterile. Therefore, we opted to perform measurements at the foot location. From a physiological point of view, the feet are known to serve as a suitable measurement location for GSR (Healey, 2011; Govoni, 2012; Gravenhorst et al., 2013; Phitayakorn et al., 2015). Further, we placed the ECG on the left side of the chest because the closer the pads are to the heart, the better the measurement (Babu Prasad, 2018). Since a cap would be too intrusive, only a limited number of channels were used to record electrical activity of the brain.

3.3 Questionnaire

Based on the different sources of occupational stress according to the SQHP – namely aspects related to work and family affairs, aspects related to specific nursing tasks and work overload and aspects related to career progression and salary – a questionnaire was set up. The head of the ICU at UZA and his ICU team then reviewed the survey. Within our questionnaire, we evaluate seven different dimensions of stress factors that ICU-caregivers face in their activities: (1) socio-demographical questions, (2) personal questions, (3) questions regarding working conditions, (4) stress-related questions, (5) fatigue-related questions, (6) questions concerning home-work interface and finally, (7) questions about career and salary.

Different types of question formulations (such as multiple choice, matrix table, slider or rank order) were used to prevent monotonous questions. This preparation of the questionnaire is required for ethical approval.

4. Discussion

The aim of this preliminary study was to construct a test setup as preparation towards the development and validation of a Cognitive Assessment Platform (CAP) for monitoring cognitive state. Ultimately, the CAP will enable identifying stressful situations that require excessive workload or degrade performance, and allow a synchronisation between the physiological data of its wearer and specific tasks.

This preliminary study applied a user-centred design approach, providing a better understanding of the needs of individuals working in a highly stressful and complex environment such as an ICU, with the aim to enhance teamwork and work efficiency. Therefore, we developed a test setup that will enable us to gain an explicit insight in the ICU staff, their tasks, and environment. The results of this study - which were required for ethical approval of our follow-up study - consisted of (1) a task analysis, which we translated into an app for easy task registration, (2) a selection of sensors to measure cognitive states at

caregivers of an ICU and (3) a questionnaire based on the Stress Questionnaire for Health Professional (SQHP).

The herein presented test setup will be applied in our follow-up study to develop and validate the unobtrusive, user-friendly CAP. The sensors that we have selected within this study will be used to design a CAP prototype. To validate the CAP prototype, experiments will be performed on twelve caregivers within the ICU of the Antwerp University Hospital (UZA). During the experiments, the caregivers will need to use the developed app to register the tasks they are performing, enabling us to link the performed task with the physiological data of the caregiver. They will then be asked to fill in the questionnaire to obtain a general qualitative overview of stress and fatigue such that we can verify whether the subjective results match the objective measurements.

To conclude, this preliminary study was essential to create a test setup, which we will use in our future study to gain insights in the ICU caregivers, their tasks, and environment. Based on these observed healthcare insights, our future design prospects are to develop and validate the innovative CAP, purposed to be a user-friendly wearable tool to enhance ICU workflow and work efficiency.

Abstract | The study is part of a food design research having the aim to assess the relevance of the olfactory experience on social development and the improvement of public health. Its immediate and primitive connection to the emotions zone establishes an experience of direct connection to motivations and desires, transporting memory to the construction of a moral consciousness about what we smell and eat, contributing to the physiological sanity although conditioned by culture. However, the organoleptic diversity in early life can condition the citizen's flexibility concerning the adoption of innovative practices and, consequently, of a greater aptitude related to public health, environmental sustainability, and, most importantly, cultural creativity. Recognizing the implication between the capacity to adopt new behaviors and the extent of children's organoleptic learning, this exploratory study (inquiry) covering a universe of 20 food smells was carried out in educational establishments, considering children aged 3-5, from polarised socio-economic groups.
The data treatment of the study led us to conclude that the most depressed socio-economic group presents a more reduced organoleptic lexicon than the other group, implying, consequently, a lower aptitude for the creative adaptation to the different, a condition for innovation.

KEYWORDS | FOOD DESIGN, SOCIAL INNOVATION, SMELL, SUSTAINABILITY, EDUCATION

1. Contextualization

> "A brain does not suit only to think but to act […] a living creature is an acting memory." (Laborit, 1979)[1]
>
> "The first brain is the gastro-intestinal one, the second one is the intellectual." (Damásio, 2019)[2]

Being invisible, the odour is potentially ambiguous, indexing itself to the memories of each existence. Smell activation in the brain takes place in the emotions' area. This immediate and primitive connection to the *complex emotions' building* (Damásio, 2017)[3] means that, from the point of view of experience, here lies the structure of one of the first senses that the human being detects which, maybe for that reason, is intrinsically connected to pleasure and the survival instinct. This is not about mere pleasure, but about pleasure as a survival function. Smell relevance and its comparison to other senses has acquired a growing prominence nowadays. According to Herz (2018), for example, in feminine gender prevails the sense of smell, to the detriment of vision, sound or touch, as its attraction highest determinant.

Birnbaum (2014)[4] observes that the sense of smell is at the origin of life, as an agent, conducting the spermatozoid to the egg, as throughout individuals' life, as an analytical "chemical laboratory", preserving individuals from toxic contaminations, thereby constituting a vital biofunctional factor, not only for mammals. However, the sedimentation of a nutritional heritage in human collective unconscious could be in the origin of the universal adherence to certain foods such as wheat (in the form of bread, for example), capable of provoking almost addictive behaviours. The neuroscientist Herz[5] identifies the sense of smell as one of the main affective stimuli: it is desire's anticipatory sense, memorizing relevant emotional experiences that will influence the preferences to the rest of our lives (Herz, 2018).

5 Rachel Herz, Psychologist and cognitive Neuroscientist, acknowledged for research on smell psychology, teaches at Brown Universit

The human being is the only animal that does not present a separation between the passage canals of air and food, though experiencing the most exquisite flavour perception[6] when compared to any other species, given the exceptional anatomy of the throat, mouth and nose trilogy[7]. In addition, the human being is also capable of distinguishing and identifying more than 1000 million odours. According to Ron Winnegrad[8] (Nguyen, 2014), the sense of smell is intrinsically linked to taste and flavour, evaluating that 90% of flavour is on smell. In that investigation field, the neuroscientist Gordon Shepherd[9] developed[10], in 2015, the human model of retronasal smell, generated among the throat, the mouth and the nose, activating in the human brain an extensive system of flavours, the origin of a new field of study, the Neurogastronomy[11] — which goal is the comprehension of the contributing factors to problems such as obesity and other eating disorders.

With this investigation we aim to understand and assess how can *food design* explore the sense of smell, as a factor of analysis, pleasure, memory and social mobilisation, not disregarding its contribution to social development, sustainability and development of a democratic regime.

6 80% of food flavour derives from its aroma (Philpott, 2015: 156).

11 A new society and an annual meeting were constituted around The International Society of Neurogastronomy. The same principles were applied to wine tasting in Neuroenology.

2. Declination from the relevance of the sense of smell on science

> "(...)Quand d'un passé ancien rien ne subsiste, après la mort des êtres, plus frêles mais plus vivaces, plus immatérielles, plus persistantes, plus fidèles, l'odeur et la saveur restent encore longtemps (...), à porter sans fléchir, sous leur gouttelette presque impalpable, l'édifice immense du souvenir." (Proust, 2012:57)

According to Deborah Lupton (1994), memory operates at several levels: personal memory (of personal experiences), personal memory of not experienced things, social or collective memory and, finally, the academic memory (of History and the past). Even though memories are not always individual, given their social character, they lay on a cultural construction that operates beyond the individual level; olfactory memories are, almost always, more intimate and personal experiences. Given the inaccessibility of each individual's intimate memory (even to the individual himself), the success of its repeated convening, triggering an emotional state of happiness might only derive from one of three situations: chance, self-knowledge or the production of new memorable pleasure experiences.

Despite odours are not savoured, they are regularly categorized into sweet, bitter or salty (Herz, 2018). Samakradhamrongthai (2020) is more rigorous in this classification, opening up the range to groups such as spicy, floral, fruity, resinous or balsamic, burnt or bad. When we repeatedly experience an aroma in the context of these flavours during the act of eating, a pairing between flavour and smell properties is established[12]. Proving the association learned between smelling and tasting, the psychologist Dick Stevenson[13] (Herz, 2018) developed a study based on participants that were unaware of the smell of lychees. To one part of the sample a lychees flavoured sweet water was administered; to the other part, lychees flavoured bitter water. The sample that tasted sweet water classified the natural smell of the fruit as sweet, the ones who tasted the bitter water associated the fruit to a bitter flavour.

A detailed analysis of literature allows us to state that for medicinal purposes sweet scents can be used to minimise pain perception. A team of experimental psychologists[14] proved this concept through the painful experience of immersing the arms in water at a very low temperature for the longest time possible. The participants who, during the experience, tolerated more than twice of the time (2 minutes) were exposed to the smell of sweet

12 For example, when one adds vanilla aroma to milk this one will stay substantially sweeter than without it.

13 Professor at the Psychology Department from Sidney University, Australia, whose investigation areas have been evolutionary psychology, food, the act of eating and applied experimental psychology.

14 John Prescott, specialist in experimental psychology, editor of Food Quality and Preference Journal, along with Jenell Wilkie, specialist in psychology, James Cook University, Australia

caramel. The group exposed to a pleasant smell (but not sweet) could only bear for 15 seconds. The origin of the results will be in the caramel smell — based on memory associations to sweet foods — setting off endorphins that will relief the pain. However, the patient who has never eaten caramel or a sweet flavour (such as crème brûlée or caramel aroma) will not benefit from the same effect. The relationships we have with smells refer to the attributed meaning by our feelings and emotions, emerging from our body or the memory of existential states (more or less positive or negative) autobiographically associated. Experiences with professional perfumers (Scala & Allante, 2017)[15] in order to the research of their extraordinary olfactory abilities[16] called brain development, by associating the feeling to the memory, and not a particular difference of nasal sensors, what conditions their creative work more to the imagination than to experience. From here we highlight the fact that the human sense of smell is a mental phenomenon and not sensory such as the one from dogs, whose caption ability is 10 times higher.

The senses of taste and smell are functionally exercised by the foetus before the birth, through the contact with amniotic fluid. The learning of flavours by the baby, before birth and during breastfeeding, explains how, apart from biological differences, cultural differences are so rooted in food preferences in early stages of life — *influenced choices* (Damásio, 2013). In addition to the taste conditioning through maternal transmission, human behaviour will develop itself oriented by the need of avoiding pain (also used as educational punishment) and repeatedly achieve pleasure (used as educational reward), in a perennial negotiation between the individual's will and the social conditioning of his behaviour. For that reason, the social promotion of a food morality (against sugar, salt, fat and carbohydrates consumption) more and more mobilised through education (against obesity and children's nutritional disorders), by condemning as guilty the "bad foods" forbidding them, will promote them as more desired ones, acquiring a status of *reward*[17]. This behavioural standardisation of the *food reward* through the right to the sweet and the fat, as a consolation for the suffered frustration, will follow all the adult life of the human being (Lupton apud James 1990:679-682) and his choices, shapping his food attitude.

15 "Unveilling our senses", documentary directed by Scala & Allante, 2017.

16 The professional perfumers were submitted to tests to evaluate the origin of their extraordinary olfactory abilities, memorising up to 5000 aromas after 10 years of experience, concluding that they were based on brain development and not on the nasal sensors.

17 Damásio reports an experiment with two individuals exposed to the resolution of complex problems. At the end they were offered a food reward and freely choose either a piece of fruit or a tasty slice of cake. The volunteer who solved the problem felt entitled to prefer the cake; the second volunteer chose alternatively the fruit, therefore compensating his low performance by choosing a less pleasant food, even if healthier. The food reward is usually sweet or high in fat, eliciting a feeling of security and indulgence.

A complex correlation of memory, olfactory experience and the individuals' emotional performance is observed, which, conditioned either by their autobiographical experience, or by numerous factors associated to education and to culture, make the olfactory experience depend more on a more psychocognitive system than a physiosensory one, though justifying a scientific approach with a semantic nature.

3. Declination from the relevance of the sense of smell in public health and social development

Considering food as an expression of material culture and, therefore, a communication vehicle with the social past (etnography), in significant forms (cooking) on the promotion of an individual or emotional experience (anthropology and psychology), it appears that the relationship between food preferences and memories can be considered *symbiotic*, once we tend to recognise as *good* (tasty) those foods that result from a certain culture, adapted to a given territory. Food rituals, seasonality, the foods' supply territory and the elective preferences of each consumer constitute the foundations of a dietary preference not always beneficial, that results from the association between memory and emotion — *we do not favour what is good, but because we like something, we will consider it good* (Espinoza, 2009).

The proposed symbiosis between memory and emotion, declined from Damásio's aphorism, *we cannot have consciousness without feelings, nor feelings without consciousness, — we cannot have emotions without memory, nor memory without emotions* — will constitute a valuable instrument not only for the social development of the most protected classes, but also for its opposite, for the stagnation of the others' more unprotected. Varied food, the openness to new experiences and flavours, the adoption of healthier systems and foods, will inexorably depend on the degree of organoleptic literacy founded in the first years of individuals' life. Individuals submitted to richer experiences will be in better adjustment conditions and, mainly, of innovation. On the contrary, individuals submitted to more limited and poor dietary practices will experience greater difficulties in transcending their own culture, demonstrating themselves less suitable to the new, the food progress and, consequently, to the adoption of healthier and more creative practices, thus prolonging the poverty cycle they inherited. The present acknowledgement elevates children food problem to a social level, being considered as a relevant instrument to guarantee democracy and, mainly, as a contribution to the construction of a society not stratified in social classes. In that sense, the phenomenon must be addressed in the structuring of education and school meals programmes, promoters of a society based on knowledge and social development.

It is, therefore, determinant the role of social policies and the appeal to education so that it contributes to a more conscious and free choice of dietary practices of the human being. As early as the eighteenth century, Savarin believed that *the destiny of nations was hostage of their dietary choices* (Loefer, 2012), supported principle by Marion Nestle (Cavallini &

Tedeschi, 2015) that highlights the importance of the speeches conveyed by state organizations and institutions concerning the approval or repression of decision-making on food.

In a study of Dazeley, Price et al. (2012) on the dietary preferences of British children[18], fat and salty foods were predominantly classified as the most popular ones[19] and vegetables as the less appreciated[20]. It appears that only 16% of children in preschool ages reach the recommended daily dose of 5 portions of fruit and vegetables (at school and not at home) — cause for alarm, given that it is in the first years that the eating habits are developed which will persist throughout life. This circumstance is common in many countries with educational social policies (integrating the food service), therefore acquiring an authority and urgency which public policies cannot neglect[21]. A detailed analysis of the researches and projects developed in this area highlights that the preference for foods such as fruit and vegetables is only developed as a result of the frequency of their administration; in other words, there is a causal link not only between food diversity and its posterior deliberate choice, but also with the age at which this exposition takes place (at the age of 2, choices and preferences that will be chosen at 8 will disseminate).

That is why it is important that parents and educators, the education institutes[22] and the local and national governance should be more and more aware to the necessity of implementing food intervention programmes, promoters of healthier and comfortable citizens, through the increase of fruits and vegetables.

In that sense we introduce the projects that have been developed in the scope of the European network of bio-canteens, a program of the European Union Regional Development Fund involving more than 400 city centres), attached to the Mouans-Sartoux model of good practice, characterised by 100% organic meals, with local products and without waste, associating the food activity to an educational function of awareness concerning food sustainability. In Portugal, the municipality of Torres Vedras has subscribed to this network, raising the quality of the 1300 daily meals (2019-2020), with which supplies its nursery and primary schools, whose funding worths currently EUR1,80, to which adds more EUR1,20 on its own resources, in order to correct the actual cost of EUR 3,00 per meal. to Laura

[18] A sample of 1291 children.

[19] Salt increases the flavour, fat amplifies the flavour and makes some possible textures appealing, acid balances and heat determines food's texture (Nosrat, 2018).

[20] In a selection of 115 foods.

[21] Anonymously, 1 out of 3 children suffer from overweight, 90% of them regularly eating *fast food* (Nuno Queiróz Ribeiro, Melting Gastronomy, 15th November 2019, Alfândega do Porto).

[22] Preschools and primary schools.

Rodrigues, Vice-President and Councillor for Education, it is urgent the importance of well-fed and nourished children so that they can develop and grow up better, emphasising that in pandemic times the school meal should be even more cherished for the probable lack of resources or economic conditions in the domestic setting.[23]

Having seen that one of the children's barriers to fruits and vegetables consumption is based on lack of knowledge and alienation of those goods, educational projects such as "Let's grow", in United Kingdom (Dazeley, Price et al., 2012), involve children at different phases of agricultural production. After 8 months of involvement, children revealed a natural predisposition to taste the foods previously unknown (vegetables and fruits) and in which culture they were involved, taking part in their plantation, growth and transformation, a determinant factor to the awareness to foods' origin.

The group that took part in the gardening project was observed eating significantly more vegetables at mealtimes at the school canteen, demonstrating that the participation in experiential activities such as the vegetable garden are, possibly, more effective than theoretical classes about healthy eating, in an attempt to encourage children to make healthy eating choices.

The results of the project, analysing the questionnaire applied to children, revealed that, after the camping, the participants were more attentive and available, asking parents for the regular acquisition of fruit and vegetables, confirming the potential of the involvement in outside interactive activities (garden, vegetable garden), originating positive and significant changes on their daily eating system.

Another children nutrition programme with successful results is the *Alliance for a healthier generation* (2011)[24], that invests on children's involvement in interactive shared reading, dramatizing vegetables and fruits as characters providing super powers, thus contributing to the modelling of healthy eating behaviours. The repeated exposition to this kind of inciting exercises will obviously involve children, teachers and parents to potentiate the tasting and consumption of new foods and, consequently, incrementing health in their participants (Droog, S., Valkenburg, P. apud Heath, H. & Kennedy, 2014).

The school model from Reggio Emilia[1], internationally recognised since 1991[2], is one of the most consistent projects in education for the development of eating (and art) skills and knowledge, motto to rethink the way how we eat, how we prepare food, how we socially interact and how we consume, requirements of children's educational system that might favour learning and social development through inclusion, participation and involvement of all its stakeholders, from coordinators to cooks. At Reggio Emilia, the kitchen is at the center

[23] 7º Simpósio Nacional "Promoção de uma Alimentação Saudável e Segura - SPASS 2020 (7th National Symposium "Promotion of Healthy and Safe diet - SPASS 2020), organized and promoted by the Instituto Dr. Ricardo Jorge, on 25th November 2020."

[24] Virtual organization involving different communities.

of school, constituting its biggest knowledge laboratory. The eating system is an important means of human affirmation and, for that reason, should be a part of the central core of children's education, transforming school into a space of social connection and sustainability.

The present national eating overwiew of low offer on fruits and vegetables consumption, excess of industrial modified products (snacks) and the growing eating neophobia in children (mainly for nutritionally good or healthy foods), reflect on the overweight of 30% of children, confirming the urgency of the execution of educational programmes since first childhood, implementing a healthier eating culture, personalised and mainly under the principle of pleasure, the use of the senses, the manipulation of raw materials and the social conviviality (Alessandra *in* Cavallini and Tedeschi, 2005).

4. Organoleptic literacy experiment: a field study with a preschool population

After the case studies about the correlation between children's olfactory emotional experience and the acquired eating acquis that will condition the future of their eating preferences in adult life, and based on the researches by Herz (2018) and Cavallini & Tedeschi (2015), we aimed to develop field study, investigating the correlation between the organoleptic literacy of 34 children (preschool aged from 3 to 5), guaranteeing their gender parity, from different economic classes. The sample characterisation was divided into two social and territorial different groups, from the district of Porto; one (School 1) located in a suburban economically deprived region (Avintes); the other in a residential urban and economically favored area at the center of Porto. The former, the social charity, a foundation, supported by the Portuguese Government, with a monthly subscription maximum cost of 120€, including food, adjustable to the economic means of the household. The meal system of this school is provided by an external company, that ensures its daily delivery.

The latter (School 2), located nearby one of the main central arteries of Porto, is a private entity with a monthly subscription of 350€, including daily eating service (plus the extracurricular complementary activities with a specific payment). Here the meals' system is managed internally and prepared at its kitchen's facilities, under the technical supervision of a Nutritionist.

The experiment consisted in a selection of 10 olfactory samples related to eating, in glass jars properly isolated from light and sight, to which children (8 subjects aged 4 years old, 5 aged 5 years old and 4 aged 3 years old) from each one of the schools, were submitted blindfolded to their smell. The samples were selected according to industrially processed

foods (vanilla, coconut, strawberry yogurts, pineapple and strawberry jellies and chocolate), aromatic herbs and spices (oregano, lemon peel, rosemary and cinnamon).

Figure 1. Samples to smell

Children were submitted to an olfactory survey structured into three questions: identification/recognition ("Do you know what this is?"), appraisal ("Does it smell good or bad?") and association of the smell to the tasting experience ("What does that remind you? Have you eaten it already?"), complemented by research field notes by the author about each subject characterization and its correlations with the environment. In the group of 17 children from the School 1, one of them presented special educational needs — though his pleasure for eating and mainly his will to taste every sample he smelt —, and other presenting respiratory problems inhibiting the full functioning of the nasal system. It was found that, in this school, children were less open-minded to the experience and its novelty, showing a state of inhibition and apprehension, by contrast with School 2, where the interest and the motivation to implement this essay exceeded the expectations, demonstrated by children's great enthusiasm and sharing with their colleagues about the obtained results. There were two children that particularly stood out in this group: one for his great olfactory and imaginative skills, deeply smelling every provided sample, as he was sharing his daily routines and eating preferences, revealing a full knowledge about every sample. The other one, eventually supported by familiar stimuli, presents a great sensorial experience with food, revealing experience in kitchen shared practices and food preparation at home (naming his parents), confessing his enjoyment for cooking.

In the Table 1 we present our results in both schools organised in this way: 0 right samples (0 right answers), 10 right samples (10 right answers), more than 50% of right answers (at least 5 or more right answers) and less than half of the right answers (at least 4 or less right answers). From the comparison of the results from both schools we recognise a difference of more than 30% concerning the recognition of a greater number of aromas at school 2, as well as the presence of an individual that identified all the scents to which he was submitted.

Table 1 – Evaluation of the extension of the scents' asset for a total of 10 olfactory samples

	Was not right in any sample*	**Was right in every sample**	**Was right in ≥5 samples**	**Was right in ≤ 4 samples**
School 1	12%	0%	41%	59%
School 2	0%	6%	71%	29%

Figure 2. Child smelling

* including the child with respiratory problems.

In the Table 2 we include both categories and afterwards we divide them between recognition of food and recognition of seasoning. In the first column we include both categories and afterwards we divide them between recognition of food and recognition of seasoning.

Table 2_ Evaluation of recognition of food and seasoning aromas for a total of 20 olfactory samples (10 + 10)

	Recognition of food and seasoning	**Recognition of food**	**Recognition of seasoning**
School 1	38%	51%	28%
School 2	54%	54%	49%

Comparing the results in the identification of food and seasoning, for 38% (School 1) against 54% (School 2), one can verify a difference in School 2 of +16% than in School 1. But, comparing only the identification rate of the group "Seasoning", one verifies a difference of +21% from School 2 (49%) than from School 1 (28%).

Comparing now the results in the identification of scents related to processed food (as, for example, sausages, scented yoghurts, chocolate, jellies), the difference of the rate of recognition — although maintaining the advantage for School 2 against School 1 — , is of lower magnitude (3%), which leads us to suppose that the major trait of differentiation comes from a more sophisticated and wider gastronomic culture of the pre-schoolers of School 2, marked by the resort to herbs and spices, granted by a more educated and protective family setting. In figure 3 we present the nature of the identified scents (experience 1 and 2) and the percentages in each sample, on both schools.

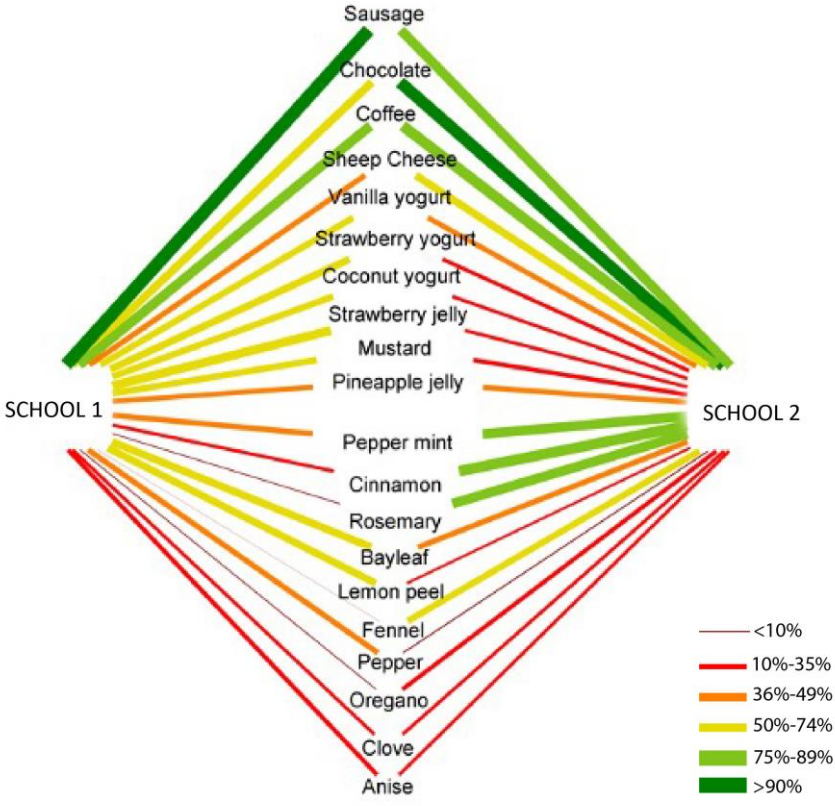

Figure 3. Percentages of each smelled sample in both schools, 1 and 2.

5. Conclusions

Although we had the intention of giving continuity to the empirical work, repeating the inquiry to validate results, the growing difficulties concerning the access due to the sanitary conditioning imposed by the covid19 pandemic would not permit us to proceed with our intent.

After observing the state of the art and the literature review (studies on children food behaviour habits) and understanding the sensorial and neurological correlations between the individuals' autobiographical experiences and the possibility of changing their food

habits, we realised that education, mainly pre-school (Carvalho and Sâmia 2016; Dazeley, Houston-Price, and Hill 2012, 2015; Geller and Dzewaltowski 2009; M. de Droog, Buijzen, and M. Valkenburg 2014), plays a crucial role in building a better future. The openness to the new and the cultural variety of sensory experiences may definitely contribute to the upbringing of more flexible, creative, free (Damásio, 2013), responsible individuals, and, therefore, more suitable for the future and, consequently, more thriving.

Therefore, recognising the implication of the skill to adopt new (food) behaviours, as a result of the acquisition of a bigger organoleptic repertoire, we concluded that the public school may have a decisive responsibility on food education and culture, as we infer from the inquiry conducted in the two schools.

This study data treatment led us to conclude that the most depressed socio-economic group presents a more reduced organoleptic lexicon than the other one, thus implying a lower skill for the creative adjustment to the different, the foundation of innovation.

This experimental study, though incipient, allows to observe other patterns, namely when comparing behaviours between genders, enabling further studies and conclusions to which we intend to give continuity.

The study observes the relevance of the olfactory knowledge, not only as a diagnostic predictor but, and above all, as an enabling feature of a bigger adaptive skill of individuals through the cultural diversity of their repertoires and childhood organoleptic experiences. If the inciting interest of this investigation was guided by a subjective intuition of its author on the acknowledged relevance assigned to smell, it now appears that its impact through food design exceeds the pure sensorial dimension, to acquire a social, sanitary and political ambition.

Abstract | Access to space is limited to humans due to a number of effects that cause anomalies on the functioning mechanisms of the human body. The rapidly growing phenomenon of space tourism, driven by the economic and commercial flywheel, contributes to medical and scientific research. Thanks to economic interests, space tourism, which seemed like a long-term project, is rapidly advancing medical and scientific research and tests.
In this avant-garde scenario, Futur.Dress is a research project that intends to develop clothing in contact with the skin and interface with the spacesuit and/or with a normal type of clothing and will have all the characteristics of a "functional superskin", suitable for future space travellers. The "superskin" will be characterized by a particular impalpable fabric, structured in such a way as to be able to act specifically on the main problems that microgravity causes on the human body, it will not be invasive because it acts as an "underwear" garment and, therefore, does not interfere the action.
The main objective of the project will be human well-being and well-being, in consideration of all the possible physiological, postural, ergonomic and perceptual changes registered so far.

KEYWORDS | HUMAN, NEAR SPACE, SKIN, BIOLOGY, BIOMIMICRY

1. Introduction

Our Age is characterized by a strong technological acceleration and sees the unfolding of a series of innovations that influence the development, expansion and human life in space. Living and producing in the Fourth Environment, therefore, becomes one of the main scientific objectives for the expansion of man in Space, through the implementation of advanced technologies expected or foreseeable for the next decades. The work for the realization of space tourism has come a long way in recent years, becoming the new world economic and commercial frontier and changing our global perceptions in terms of adaptation, permanence and procreation in space.

The scenario described is the reference for the development of the research project which involves the design of a structured underwear for the space that enhances the main characteristics of a real "super skin", to protect the human body from problems deriving from the effect of microgravity on the human body, in a natural and non-invasive way.

The focus of the research, therefore, is the adaptation of the human body in a new environment characterized by microgravity. In addition to providing the tools of critical analysis and interdisciplinary methodology, the design project is at the centre of the creation of a 'new skin' which will constitute the “sensor suit of the future”; an impalpable film that will protect the human body, thanks to natural principles and an imperceptible set of interconnected sensors.

Man and his actions are immersed in an open system, therefore the dress is also seen as an underwear object capable of continuous exchanges with the new environment as well as relational, economic and social context to be built future.

The dress will be a functional and performing underwear garment characterized by a specially designed modelling, which takes into account the principles of biodesign and is based on the criteria of biomimetic design, inspired by the functioning and structure of human skin. The observation of the mechanisms of the living, described in the broad scientific narrative, represents the condition of the existing to be imitated because it has demonstrated the greatest expressive creativity of the potential of complex phenomena. Biology has observed, collected, catalogued and classified the phenomena of life for decades. Being able to take advantage of biological knowledge to reproduce natural solutions and processes in the design of clothing opens up a broad scenario for imagination and experimentation.

The "superskin" will present a particular impalpable fabric, structured in such a way as to be able to act specifically on the main problems that may occur during the stay in space, becoming the means of safety and the guarantee for the well-being between the human body and the space environment.

In order to obtain maximum results, the work carried out to date has been conducted in close collaboration with a team of medical researchers, cardiologists and dermatologists for

the medical-scientific part and a team of physical, mechanical, aerospace and textile engineers for the specific design of the material and sensors to be integrated into the garment to be made. The "superskin" will also be designed according to an anatomical study distinguished by gender, with more elastic zones to guarantee the compression movements bands to provide micro pressures on the human body and control the diversification of fluid distribution (in space they tend to move towards the upper part of the body).

The objective of the research will be to design a clothing solution that is like a "superskin" and has safety and fit requirements through an "anatomically correct, structured and performing design".

2. Research development

The first phase of the project development focused on theoretical research aimed at analyzing the effects that the human body undergoes in space. Venturing into the space environment has proven negative effects on the human body. Living for a short or long period influences the functioning mechanisms in three different ways: loss of proprioception or loss of the ability to perceive and recognize the position of one's body in space; changes in fluid distribution; deterioration of the musculoskeletal system (for long-term permanence).

These effects are connected to a series of other dynamics that could jeopardize the well-being, safety and success of the tourist's stay in space (tourist 2.0). Starting from these assumptions, in-depth medical-scientific studies were conducted on the various causes that microgravity causes, carefully analyzing the standard health values for both a man and a sample woman and comparing them with the results of the experiments conducted and published on the website of NASA and ESA.

The microgravity we are dealing with in this study is that present in the Near Space, that is the region of the Earth's atmosphere that varies from 10 km to 200 km above sea level, included in the low Earth orbit. The term "microgravity" refers to a state in which the absence of gravity is not perfectly achieved due to small residual forces, such as air resistance or solar pressure. Microgravity is expressed as a fraction of g, where g is the gravitational acceleration on the Earth's surface, with an average of 9.81 m/s 2. In this environment, it has been observed that a change of cells, tissues and organs adapts to the conditions in which the unaccustomed body on Earth is found.

Without the effects of gravity, in fact, the functions of the human body undergo some changes in the posture and functioning of bones and muscles. The muscle/skeletal system is in fact no longer necessary to maintain posture and the muscle groups used to move in a weightless environment, differ from those required in terrestrial locomotion. Another problem encountered by astronauts is skin reactions and a series of pathophysiological changes, most likely due to the lack of gravity. Skin problems play an important role alongside those related to circulation and balance disturbances. In addition to itching and

dryness of the skin, thinning of the dermis and increased sensitivity combined with delayed wound healing and in part also a greater tendency to skin infections have been found.

From this first analysis, the network of voluntary collaborations, specialists and specialist researchers in this field was configured, to give answers in a targeted way to pad any problem highlighted in the superskin project. The specialists involved in this project are: dermatologists, to deal with the problem of dry skin; cardiologists and hematologists, in order to understand cardiac function, blood pressure in stressful conditions or in conditions as similar as possible to the space environment; textile engineers, to characterize an innovative and functional advanced non-woven fabric; aerospace engineers, to understand in more detail some dynamics of the ISS (International Space Station); physical engineers, to detect new data (e.g. skin surface temperature) and technologies, Peltier cells and nano-textile sensors to be integrated into the "superskin".

2.1 State of the art technology and knowledge transfer

Having established the ecosystem of interdisciplinary collaborations, the first step was the analysis of the human body from an anatomical point of view, with particular attention to the muscle fascia and, in parallel, an in-depth analysis of biomimetics. The anatomical features examined in the first step were: the control of the diversification of the distribution of fluids to counteract the problem of proprioception. For this purpose, the focus has been on the compression to be implemented on the body to mitigate the effects of the different distribution of fluids.

The research was therefore developed on the basis of the prevention methods used in sports for limb, tendon and muscle injuries, such as braces and bandages. Attention was focused on the bandages, in particular the functional bandages, of the *Theratogs TM system* and *Kinesio Taping*. These latter adhesive bandages, in particular, relieve the physiological load by exerting traction and transferring force directly to the skin. The bandage can act both at the joint and at the tendon-muscular level, depending on the application technique for unloading, stabilization, support or compression.

Theratogs is a system used to facilitate movement and postural alignment; takes on the function of a second skin with a totally adaptable strap system. Provides a foam lining, breathable and comfortable. In addition to the strap, the straps offer rigidity on the vertical axis to improve joint balance and flexibility on the horizontal axis to ensure fit and comfort.

Kinesio Taping is a taping with therapeutic and biomechanical effects. It is a hypoallergenic tape with excellent elastic qualities, has the same thickness as the leather and is resistant enough to withstand for several days even in the presence of sweat and the use of showers. It works with the fascial, lymphatic and muscle/skeletal systems. When the tape is applied to the skin in a normal position, an effect called "convolution" occurs, so as soon as the body moves, the tape acts as a pump, continuously stimulating lymphatic circulation and muscle correction.

One of the characteristics of Kinesio Taping is to improve the perception of body movement by counteracting the swelling of the tissue due to compression. Considering that the human body is a perfect machine and capable of adapting to extreme environments autonomously, the first hypothesis is that of acting in a completely natural and non-invasive way, providing support to the human body through the study of structured modelling, designed *ad hoc*, based on the Kinesio system. The theoretical reference to biomimicry has also provided the elements for the functional characterization of the superskin.

Life is "the condition of organisms endowed with a specific form, a specific chemical constitution, able to maintain themselves in a situation of dynamic equilibrium, i.e. to have a constant internal environment despite exchanges with the external environment (homeostasis) and to reproduce these properties in other similar organisms" (www.treccani.it/enciclopedia/tag/vita).

The most interesting feature is that nature not only undergoes changes with time, but also evolutions and innovations. The mechanisms of evolution are complex and very slow and include several aspects. The uniqueness of each individual is one of the most ingenious expedients of this mechanism, because each specimen is in fact an experiment.

In an ever-changing ecosystem, the only chance of survival is in change. In each generation a particular character (perhaps a mutation) can manifest itself that, between attempts, mistakes and lucky coincidences, can become fundamental to survival in a changed environment and then spread in the following generations.

The biological strategies that we can imitate manifest themselves at various scales, there are examples of materials inspired by nanometric structures, but it is possible to inspire the design of the functional underwear to the resilience of macro-organisms such as prairies or Mediterranean scrub.

There are solutions more suitable for experimentation in the chemical-physical field, others in the technological field. Imitations can be of interest to living organisms themselves, but also to their group behavior, or one can draw inspiration from the constructions that animals erect as a refuge or den, as an indirect imitation of biology. These biological strategies have been modelled and perfected over millennia and reach high performance levels.

"Biomimetics introduces us into an era based not on what we can extract from nature, but on what we can learn from it. Shifting the focus from learning about nature to learning from nature requires a new method of investigation, a new set of lenses, and above all a new humility" (Benyus, 2011, p. 35).

The in-depth study of biomimetics marked the transition to the second phase of the development of the research project: the study and analysis of the structure of the fabric that will constitute the super-skin and the first hypothesis of the morphology of structured underwear.

Different living beings such as plants and trees are taken into consideration as examples to be imitated to increase the positive effects of some solutions adopted as we have seen in Kinesio Taping, especially for body thermoregulation. For the superskin project, we proceeded by analyzing the structure and functions of human skin. In fact, the concept of superskin tends to highlight and increase functional and behavioral characteristics already. present in human skin.

The skin, also known as the integumentary system, is a tissue of separation between the individual and the environment and, acting as a mediator, performs multiple functions: it protects from harmful external agents and constitutes the first defense barrier of the organism; detects changes in temperature and pressure; controls evaporation; regulates body temperature, dispersing heat or reducing heat loss through a system of vasodilators or vasoconstrictors.

Starting from the assumption that the imitation of form and function is the basis of most of the projects defined as biomimetic, the creation of a fabric structured in three different layers, inspired by the structure and functioning of human skin, was hypothesized. The consistency will be slightly porous, to contain substances capable of maintaining skin hydration; the thickness will be a few millimeters and will incorporate micro-sensors to constantly monitor the health of the tourist, in a completely invisible and non-invasive way. This innovative fabric will form the new separation membrane between the human body and surfaces or the external environment.

As for the morphology of structured underwear, in order to obtain a more efficient emulation, the imitation of the process that leads to a particular functional form and the imitation of the logic of the ecosystem, or an open system full of connections with elements of the context has been taken into account.

3. The interdisciplinary network

The third phase of the development of the research involved consulting with specialists, doctors and engineers, in order to obtain more results on the basis of the assumptions endorsed. The first consultation was on skin dryness with the dermatologist of the Policlinico Nuovo of Naples: Dr. G. Argenziano. Together with him and two other collaborators: Dr. Elisa Fulgione and Dr. Caterina Fulgione we examined in detail the causes of epidermal dehydration by examining a study conducted by the Institute for Experimental Dermatology, University of Witten/Herdecke, Witten, Germany.

Clinically relevant side effects on astronauts' skin in space play an equally important role as blood vessel-related side effects. It has been reported that problems related to dry skin, skin irritation and dermatitis occur with a frequency of 39 % over a short-term space stay. To date, there are no extensive studies on the effects of a stay in space on human skin and in particular on skin changes during a long-term mission. Ultrasound measurements have only

been performed during a short-term mission, i.e. under the influence of ship alteration. Further numerous examinations concern the influence of the absence of gravity on the vascular system. Naturally, the physiological measurements of the skin are also influenced by an adaptation of the vascular parameters to the absence of gravity.

Within about 3-5 days, however, the displacement of the fluid (blood and tissue fluid) is completed. The adjustment of the blood composition takes about 4 weeks. Epidermal measurements have provided evidence of thinning of the stratum corneum and prolonged cell moulting time from the basal layer to the stratum corneum. The results obtained from the tests revealed a high rate of skin dehydration, epidermal thinning, dryness, itching, thinning of the dermis, increased sensitivity, increased tendency to skin infections, delay in wound healing, loss of elasticity and mild skin ageing.

Note the results of this first study, together with Dr. Caterina Giorgio and Dr. Elisa Fulgione we considered the option of treating the parts most affected by the problem (legs, arms, forearms, feet, groin) with highly nutritious and moisturizing substances such as ceramides, fatty acids and glycerol. In particular, the use of glycerol was the most recommended as it helps to maintain skin hydration for a long time and therefore to slow down the appearance of signs of ageing and skin deterioration; glycerol also helps to stimulate cell renewal.

A one-sided treatment with a skincare emulsion while in space would lead to an improvement in the hydration of the horny layer and an improvement in the barrier function of the epidermis. However, in order to obtain more precise results, additional tests are necessary, especially with a larger number of test subjects, using optimized test conditions and additional measurement methods. In this way, side effects on the skin related to a long-term stay in space can certainly be minimized and general medical risks can be recorded through physiological skin parameters.

This applies especially to the causes of skin changes, e.g. the influence of weightlessness, which can then be determined. Another suggestion, therefore, was to act preventively while waiting for future results, preferring tissues that are antibacterial, antifungal and antiseptic, as conditions in space tend to proliferate bacteria and try to develop a nano sensor that has the same function as the chronometer that can be used to monitor skin health constantly.

3.1 Design for Spatial Human Beings

The conquest of Space by man, from the Apollo 11 mission that allowed the first human being to set foot on the Moon to the last flight of SpaceX, has known various phases projecting man towards boundaries once considered utopian and impossible.
Today we can consider ourselves humans living in the *New Space Age* and "space tourism" is inserted as a luxury experience accessible to the elite classes of planet Earth.

The tourists 2.0 in fact can be defined as users looking for unique travel and experiences, exclusive and far from the old paradigm of mass tourism; They use space as a form of

consumption, leaving traces of their status not only terrestrial; They fit into a market governed by new social and cultural trends and that determines new needs.

They wish to live an extraordinary and otherworldly experience to dissociate themselves from the terrestrial habitat: they seek new spaces, configure new temporal dynamics to define a new normality.

So defined according to recent literature, the Space Hub has opened new cultural images of space and has also caused fashion design and space wear engineering to intervene in the configuration of a true space wear system, *spacewear.*

The design and implementation of a 2.0 tourist-centric clothing system is based on research and experimentation of new methodologies that respond to specific criteria dictated by microgravity and weightlessness, as well as conditions that may occur during the short stay in aerospace. To maximize safety conditions by advanced and customized materials or electronic components using innovative and smart textiles, the human being can face the foreign environment that involves the so-called space pathologies, i.e., alterations in his/her vital functions.

The spatial clothing system for the 2.0 tourist composed of several parts, must also express the luxury status of the user that translates into an original design, comfortable but also sophisticated while responding to the limited aesthetic concept of the technical components.

The first design phase involves the modeling of a space undergarment, the "super skin", which based on the principles of biomimicry, configures a base layer in close contact with the body. This is followed by interchangeable elements that define a mid-layer and an outer layer: a jersey, a pant and a jacket replace the current space suits, in a configuration specifically designed to ensure maximum comfort and convenience during non-vehicular activities, configurations made possible thanks to the symbiotic relationship between the field of wearable technology, computer science and evolutionary design of space systems where the multidisciplinary nature of the project collides between the subjects of engineering, design, medicine and ergonomics.

The design of the individual items that make up the system, consider the *Mechanical Counter-Pressure*, a specific technology still in its experimental phase (MCP) that replaces the pneumatic pressurization used in previous spacesuits. Using this technology, mechanical counter-pressure is applied directly to the body with temperature management mapped to the body to provide perfect heat and humidity management while preventing overheating or cooling. The system so configured would bring increased flexibility, dexterity, and comfort as well as ease of donning and doffing of parts.
The configuration of the space clothing system is intended to redefine design practices in terms of type follow function" concept of garments that conform to the exact shape of the body, for precise innovation that best interprets the "from fit, under critical conditions where locomotion and mobility are a top priority as is decreasing weight and equipment. The application of ergonomics requires considering human capabilities, abilities, limitations

and needs with a design of new clothing elements that does not find superstructures or superficiality but takes up the concept of Bauhaus not as reduction and minimalism but simply of consistency from design to prototyping.

3.2 Discussions

From this data, a plot has been developed of how the amounts of glycerol can be distributed over areas of the human body (Figure 1). The second consultation was with the research cardiologist, Dr. F. Coppolino. During the meeting with Dr. Coppolino, questions were also raised with fellow dermatologists in order to provoke a debate on the same issues but addressed from a cardiovascular point of view. All the examples of monitoring instruments used on the International Space Station in order to control the vital parameters of the subjects performing medium and long term missions in orbit were exposed. Also in this case, in order to obtain precise data on cardiac function in space, we made use of some studies carried out by NASA and specialist institutes on heart pressure. It is well known that the absence of gravity during short-term space flights (from days to a few weeks) causes a displacement of 2 litres of blood and fluids from the lower body segments to the upper part of the body, which is accompanied by a heart increase of 20%, despite an unchanged or reduced heart rate. However, blood pressure remained unchanged or decreased (mainly diastolic pressure) and heart rate decreased by up to 15 beats per minute during weightlessness, despite maintaining high sympathetic nerve activity. Another analysis carried out concerned about the difference in behaviour between men and women in space.

Tests carried out by NASA showed that women are subject to orthostatic intolerance linked to vascular problems that occur in microgravity conditions and have a greater loss of blood plasma volume. The response to the stress they undergo while onboard the ISS results in a more pronounced increase in heart rate in women than in men, while the latter responds with an increase in vascular resistance.

With Dr. Coppolino, therefore, needs in terms of spontaneous adaptation of the body to the new environment were highlighted, which should not be limited with a preventive intervention in order not to inhibit natural reactions that are instead useful to the body; therefore it was decided to pursue the path of preventive rather than functional monitoring. Having selected some preliminary parameters to be included in the functional clothing that is being designed, a functional/adaptive textile project has been configured with a predominantly "diagnostic" and then adaptation purpose.

From this data, a trace of how the patches for cardiac and pressure control can be positioned on the human body zones has been elaborated (Figure 2). The third consultation was with engineers M. Masullo and M. Scorpio. After the first analysis of all the results obtained and the problems on which we are proceeding, it was proposed to intervene through a specific sensor that can monitor the surface temperature (F-skin), creating a Peltier effect to calibrate the heat. Through this thermoelectric phenomenon, originating

from the Peltier cell, the electric current flowing between two different metals or semiconductors placed in contact produces a transfer of heat.

From this data, a trace of how the sensors for temperature control can be positioned on the human body zones has been elaborated (Figure 3).

4. Conclusion

Being a research project still in the development phase, there are no conclusions on the project itself but experimentation still to be carried out and the design phase to be started. The study converges on the problems caused by microgravity on the human body and biomedical research turns towards solutions to support and control them.

The research involves the development of a specific fabric: a type of impalpable non-woven fabric with microencapsulation of glycerol that will allow the dermis constant hydration. The design of the structured spatial underwear includes the specific study of new high-performance modelling, studied on the basis of biomimetic design.

The aforementioned will be presented as a "superskin" modelled in such a way as to follow every movement of the body and consider all possible physiological, postural, ergonomic and perceptual changes, giving comfort and safety to the tourist 2.0.

About the Authors:

Maria Antonietta Sbordone Associate professor in industrial design deals with research on innovation in fashion and design eco-systems linked with the circular economy in goods and service productions. Tutor of the research proposed in this paper, contributes to the assessment and to the conceptualization of the research theme, building the interdisciplinary panel of experts to have a large discussion to achieve the established findings.

Ilaria Giampetraglia Master' degree in Fashion Ecodesign carries out research of the paper proposed at Officina Vanvitelli hub of the Department of

Architecture and Industrial Design of the University of Campania "Luigi Vanvitelli".

Alessandra De Luca Master' degree in Fashion Ecodesign at the Department of Architecture and Industrial Design of the University of Campania "Luigi Vanvitelli".

Acknowledgements: We would like to acknowledge the following experienced professionals who follow the research and with their precious collaboration we have created an interdisciplinary network, which are: the dermatologist of the Policlinico Nuovo of Naples: Dr. G. Argenziano, and two other collaborators: Dr. Elisa Fulgione and Dr. Caterina Fulgione; cardiologist, Dr. F. Coppolino; engineers M. Masullo and M. Scorpio.

Although the authors have shared the general line of the paper, however, the chapters are attributed as follows.

Maria Antonietta Sbordone has drafted the following chapters: Abstract; 1. Introduction; 2. Research development; 3. The interdisciplinary network; 3.2 Discussions; Conclusion.

Ilaria Giampetraglia has drafted the following chapters: 2.1 State of the art technology and knowledge transfer.

Alessandra De Luca has drafted the following chapters: 3.1 Design for spatial human beings.

Abstract | As designers we have an obligation to design taking into consideration the complexity of reality; the only way to face it is to adopt a multidimensional and dialogical design thinking. If it is true that the goal is to understand the qualities of the complex system in which we live not as a simple sum of its parts but as a system of complex interrelationships, where the qualities derive from the relationships and interrelationships between the components of the system itself, the quality of a product-system is measured not so much by its ability to create useful value by its individual parts, as much as its ability to create relationships between its components. The paper will present a research project where products equipped with technology have been created to make the human, technological and natural systems interact [1].

KEYWORDS | COMPLEXITY, SYSTEM, PRODUCT DESIGN, SUSTAINABILITY, TECHNOLOGY, IOT

1. Introduction

In terms of sustainability, designing for the complexity of reality is, according to many scholars, the only way to achieve a correct balance with the nature that surrounds us. The human condition, however, is at odds with the second law of thermodynamics according to which the energy used for any process is transformed into entropy; as Rovelli argues (2017, p. 140) the entire history of the universe is characterized by the constant increase in entropy. All living things are composed and defined by similar processes that trigger each other. For example plants thanks to photosynthesis collect solar photons, animals (including men) feed on low entropy by eating. As Rovelli argues (ibid., p. 141) within each living cell the complex network of chemical processes is structured in such a way as to allow a constant increase in entropy. Life is a complex network of interrelationships between heterogeneous elements that stands and evolves thanks to the constant increase in entropy.

As McDonough W. and Braungart M. claim (ed. 2013, p. 99) only two essential elements make our life on earth possible: the earth (mass) and the sun (energy). The sun is the only thing with constant entropy (Korhonen J. et al., 2017, p. 42 and Morin, ed. 2015, p. 336) which thanks to photon irradiation allows life on earth and shows the most admirable example of natural and spontaneous organization.

> "This fabulous machine that made itself, in and through the fire, and not only once, thanks to an incredible stroke of luck, but billions and billions of times - this machine swirls, manufactures, works, regulates itself without a convector, engineer, specialized parts, without program and without thermostat"(Morin, ed. 2015, p. 185) [translation by the author].

The action of man, unlike that of the sun, has instead demonstrated systemic planetary limits (Meadows D. H. et al., 2004) which require us nowadays to review and redesign our development model. As awareness of the damage produced by anthropic force on natural systems has matured, in recent years we have been witnessing important changes in the way we think, design, produce and consume.

On the basis of this consideration, it could be said that the role of the designer may be to build relationships in antithesis to the parcelling out of areas and knowledge.

Designing the complexity of reality does not mean guaranteeing the development of a single system (economic, for example), but of increasing the capacity of relations between systems (social, cultural, natural, political, economic), making them cooperate as an organic whole. Design, as Paola Antonelli (2019) argues, is a mental and political form just as nature is. According to the renowned curator, design and architecture can help us deal with a life that also deals with other species and that looks beyond immediate interests.

In terms of sustainability the world should be considered as a set of complex systems interacting with each other. As Thackara (2008, p. 13) argues, as designers we must face the

imbalance of multiple systems that interact with each other such as energy, climate, food, culture.

Capra F. (2013) introduces the concept of qualitative growth which, in society, ecosystems and living organisms, consists of an increase in complexity, refinement and maturity. The concept of qualitative growth must therefore be understood as in biological systems, where there is quantitative growth when an organism is young and qualitative growth in the next phase, characterized by slowness, maturation and decline or, in the case of ecosystems, with 'succession' and therefore an increase of complexity. Understanding the system in which we design as a complex set of heterogeneous relationships including technological, social, cultural, biological aspects could lead us, taking up the concept of Morin[2] (ed. 2015, pp. 336-346), to conceive active self-producing organizations and consequently generators of the negentropic character necessary for greater sustainability.

If we consider the system that is created between people, nature and digital technologies we can consider it as a complex system (Gandolfi, 2008) which includes within it complex elements which act in a differentiated but unitary way. Systems are, as claimed by Ghajargar M. et al. (2018), to a large extent, related to the relationships between people, activities, objects, technologies and places. Recent digital technological developments have increased the daily use of "intelligent objects" which systemically interact with each other and with those who use them. However, as Ghajargar M. et al. (2018) argue, very often the design of IoT devices focuses on the product rather than on the relationships it generates between people and with other products. The relationship of reflection that could be established between the user and the product (material and immaterial) according to the authors could bring benefits in terms of sustainability (Baumer et al. In Ghajargar M. et al., 2018).

In this scenario, design can certainly make an important contribution especially thanks to the ability to adapt and integrate between and in different types of knowledge. The disciplines of the project are transforming very rapidly in recent years, by their nature they are called into question whenever there is a need for innovation. In particular, today the progress of technology on the one hand, which has led some technologies defined as "enabling" to have very low costs (commodities) and an exceptional diffusion (Celaschi, Di Lucchio, Imbesi, 2017), and the development of science on the other , in particular biotechnology, have offered and continue to offer design important challenges of development and connection with other sciences.

This article will present a recent research project relating to an outdoor furniture system where different systems dialogue: the 'vegetable', the 'social', the technological (cloud and sensors) and cultural systems. The project presented therefore attempts to keep the social, cultural, technological and biological aspects together to make them act as a single hybrid system (human - technological - botanical) which aims to regulate itself for a common goal, life.

2. Natural forms to emulate

Looking at nature to learn its complexity developed over billions of years is a challenge that man has proposed for centuries (Mascitti J., 2018, p. 17). From the preliminary studies of Papanek (1973), to the scientific theories of Benyus (1997), thanks to the important scientific advances, we have now come to know in depth the structures, processes, logics and operations that underlie the natural world (Ranzo P. in Langella C., 2007). The close and microscopic point of view that scientific studies have reached are allowing us not only to observe nature as a source of inspiration but also as an instrument of innovation (Langella P., 2007, p. 20).

After all, the human system is in continuous interaction, even involuntary (positive and negative), with natural elements and precisely for this reason a design that brings the human system closer to the natural and biological system could be a promising road to greater sustainability.

The idea of establishing a dialogical relationship with the plant system seems absurd and science fiction, but recent discoveries confirm that interspecies forms of communication already exist in nature (Beiler K. J. et al. 2015). For example, if we consider the 'forest' ecosystem we can see that under the surface a vast and interconnected network of life connects trees through their root systems, but above all through other species: mushrooms. As the authors explain (idemI) the process begins with the oldest and tallest trees in the forest, these have greater access to sunlight and through photosynthesis, they produce more sugar than necessary. Mushrooms, which need sugars to survive, develop most of their body underground, which is made up of a dense mass of threads called 'mycelium'. This grows in the root system of trees to absorb excess sugars. In return, the mycelium supplies the tree with the nutrients it needs from the soil. This symbiotic relationship is known as mycorrhiza which derives from the Greek words myco = mushroom and rhiza = root. These tree-to-mushroom relationships connect the trees of the forest together, forming an underground communication network to exchange water and nutrients useful for growing sprouts and even send warning signs when plants are threatened (TED summit, Simard S.W., 2015) .

To get a better picture of these relationships, the team of researchers from the University of British Columbia used DNA analysis to map a fungal network in an area of the Canadian forest. Surprisingly, they found that on average each tree was connected to forty-seven other plants. Even fossil remains have been found which confirm the existence of mycorrhizae already 450 million years ago, at the same time as the appearance of plants on the emerged lands, and it is believed that they were fundamental in the process of colonization of the continents and the development of life (Beiler KJ et al., 2015).

Since design has the ability and the duty to set in motion dialogue processes between the parts of a system and the surrounding environment, affecting society through the production not only of objects but also of new relationships and socially more sustainable

behaviors (Rossi M., 2014), isn't studying this type of exchange a clear example of interspecies communication where IoT could help us to achieve greater sustainability?

3. The project

3.1 Interdependence between man and plant. a mutualistic relationship to be rebuilt.

In line with the definition of Smart City issued by the European Parliament (2014) "A smart City is a city seeking to address public issues via ICT-based solution on the basis of a multi-stakeholder, municipally based partnership" the project invites people to get closer to nature and proposes strategies for the development of a balanced urban ecosystem. The goal is to stimulate human-plant relationships by reconstructing, thanks to IoT technologies, the bond that makes these two life forms a single biological machine.

If, as Edoardo Fleishner (2014) says, the future belongs to the metropolises, cities and villages, then they must cross-mediaialize and it is only in this way that they become smart. The first step towards cross-mediation is awareness, that is, that everyone is aware of the ongoing process.

This process, according to the author, consists in the construction of the nervous system, that is, the brain, of cities. For example "In Italy this evolution finds fertile ground, because we are already a pre-cross-media people, that is webbico, social, mobile and multiscreen, but above all creative" (Fleishner, 2014, p. 15). The designers therefore had to start confronting a more diversified design reality, considering the product as part of an eco-system, adopting a multidisciplinary approach and interrupting that designer-craftsman relationship typical of Italian design (idem). But what exactly does being smart mean? Considering the origin of the term, in the IT field, being smart (intelligent / brilliant) means being able, within a complex reality, to process the information available and consequently make the correct choices. So what is smart design, in the true sense of the term?

> "Smart design is the one that finally has the courage to take on all the ethical and social implications of design to improve the reality that surrounds it, analyzing the systems behind the new contexts of life and creating objects that can promote and convey behavior environmentally and socially more sustainable" (Mometti M., 2014). [translation by the author]

3.2 SMAG PROJECT (Smart Garden)

SMAG project, coordinated by the technological leader Nuvap Srl and with the supervision of Distretto dID (Distretto Interni e Design), involves two research entities, DIDA Department and DAGRI Department, and two companies in the stone sector: UP Group Srl and Arredo di Pietra Srl.

The project involves the creation of a hybrid product / service system that will allow companies, including traditional manufacturing ones, strongly focused on the product, to develop new paradigms that are attributable to the Smart Service Welt (World of Intelligent Services) much more based on the relationship with the user, and above all it will allow to combine products with third party services on digital platforms, contributing to the creation of new digital infrastructures: intelligent spaces (smart spaces) or environments where objects, equipment and machinery that are intelligent and enabled to connect the internet, connect to each other.

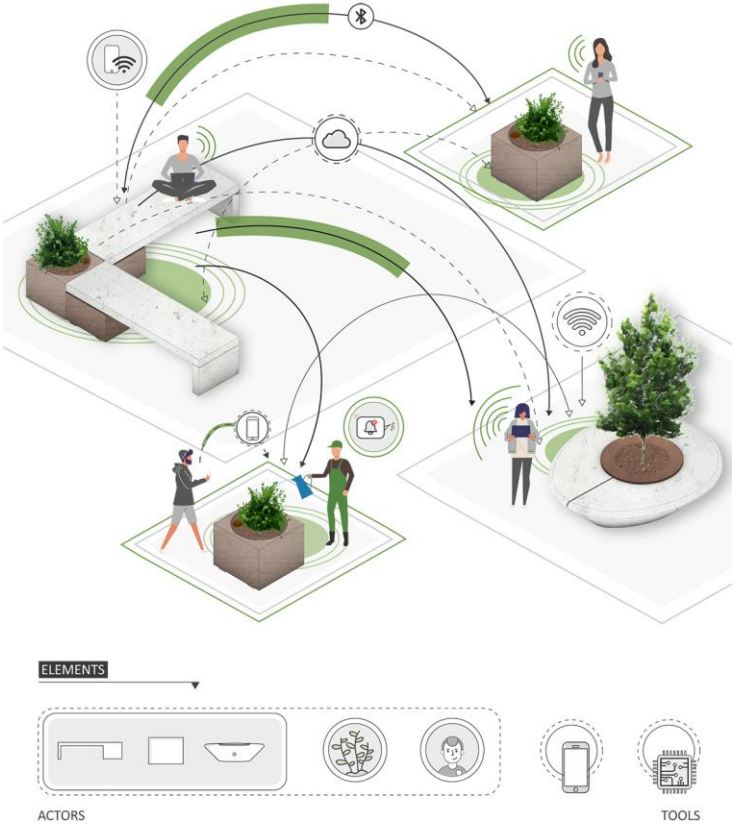

Figure 1. In figure no. 1 we see how the technological set-up relates the needs of the vegetal system with the inhabitants of the urban park or with maintenance workers such as

gardeners (product, people, plants and tools - sensors and devices -). The vital parameters of the plant and air quality are collected through sensors integrated into the furnishings and sent to the cloud. The user or the park maintainer can access this data at any time through a specific app, which informs him about the quality of the urban air and the health of the plant. In case of need by the plant or if certain air quality parameters are exceeded, the application will warn the user.

The project has been developed strategically on two market sectors: urban furniture for public spaces and that for private outdoor spaces. As regards the public sector, two collections of Rapolano travertine objects belonging to the same system have been developed. Both in the Alessandra Galli's concept 'Water Value' (Fig. 3) then in the Mirko Romanelli and Jonathan Lagrimino's 'Litus' collection (Fig. 4) the objects were designed not as mere isolated products but as part of a product-system, small synapses aimed at building a distributed network of objects in the city that exchange information between them using WiFi and bluetooth technologies. Everything can be monitored through a WEB management interface (Fig. 3, right). The goal is in fact to build a sort of widespread intelligence capable of self-regulation and regeneration following those homeostatic principles that are the basis of any living being. The urban pots that house the plants are therefore equipped with sensors that measure the parameters of the soil from which the needs of the plant are deciphered. These data are sent to the Cloud and the intervention of man takes place therefore to satisfy the specific need, but what does the man get in return? Nothing but the oxygen it needs to live (Mancuso, 2019, p. 87). The shape of the product (Fig. no. 2) in particular is designed to accommodate a medium-sized shrub and also provides a sitting space. The surface of the seat is manufactured with an inclination of 2% towards the interior in order to assist rainwater in a channel that supplies three underground terracotta pots (Fig. no. 2). The "olle" (trans.: jar) method, a multi-millennial irrigation technology, keeps the soil moist but not wet and this discourages the proliferation of bad herbs; in addition, the water is distributed directly to the root level, avoiding surface washout and evaporation. Each jar, thanks to the porosity of its walls (porosity is determined by a percentage of organic substance in the clay mixture that disappears during the cooking phase), keeps an area moist with a diameter approximately equal to three times its size, for a period that varies according to the season and the place. The design of these elements for self-irrigation is designed following the physical law of Darcy ($\Delta P = k \cdot q$) which determines the motion of a fluid (in our case rainwater) through a porous medium (terracotta). In dry periods, when the water reserves run out, an ultrasound sensor, placed inside the jar, signals the need for irrigation and a dripper provides the refill, ensuring constant irrigation. When the volume of soil becomes saturated in rainy periods, a canal, also inclined at 2% towards the outside, drains excess water avoiding compensation for the roots.

"Water Values" and "Litus" therefore become objects aimed at triggering homeostatic phenomena; where homeostasis is understood as the aptitude of living organisms, whether they are cells, individuals or communities, to maintain their characteristics in a state of equilibrium with varying external conditions: the living being (in our case the cities) a open-

system, the maintenance of internal conditions is carried out by automatic mechanisms (homeostatic devices, in our case the furniture system) which regulate internal flows through the system itself. An example of this is the ability, typical of mammals and birds, to maintain the optimum body temperature as the external conditions vary and the quantity of heat produced in the metabolism processes. This project therefore has the ultimate goal of

Figure 2. In Figure 2 we see the integration of the technological set-up within the urban furniture element. Rainwater irrigates the underground jars through the inclined plane and the system of channels (a), a channel inclined towards the outside allows the water to flow out when the containers are completely full (e). The jars uses the principle of capillarity feeding the plant in an optimal way (b). In hottest months, when the jar is empty, an ultrasonic sensor will inform the user to fill it manually or will activate an automatic filling system (c). Inside the pot there is a soil humidity and temperature sensor that allows the user to monitor the parameters (d). On the side there is a control unit designed to process data relating to the quality of the air and soil (f).

eradicating the old city / countryside, built environment / natural environment to make man and the plant coexist, promoting exchanges and synergies between these two forms of life. In parallel, has been a collection of objects for the private sector. The SMAG project involves the development of a system of intelligent furnishings for the care of the home garden. Also in this case, the objects have been designed to improve the relationship between man and nature and to build forms of interaction between them. The project (fig. no. 6) is built on a fairytale (Snow White and the Seven Dwarfs, concept by: Giacomo Da Re) and each environmental parameter is communicated through feedback associated with a specific 'nano' (trans: dwarf). For example, the air quality will be reported by Sneezy (Sneezy / air quality, Dopey / air humidity, Grumpy / atmospheric pressure, Sleepy / soil humidity, Bashful / temperature). The sensors for the evaluation of environmental parameters (PM10, PM2.5 PM1, VOC, CH4, CO2) and the control unit are all contained within the 'Doc', the central element of the collection, slightly larger than the others. These sculptural elements conceal the irrigation system beneath them, which is activated when the soil moisture sensor signals dehydration of the soil.

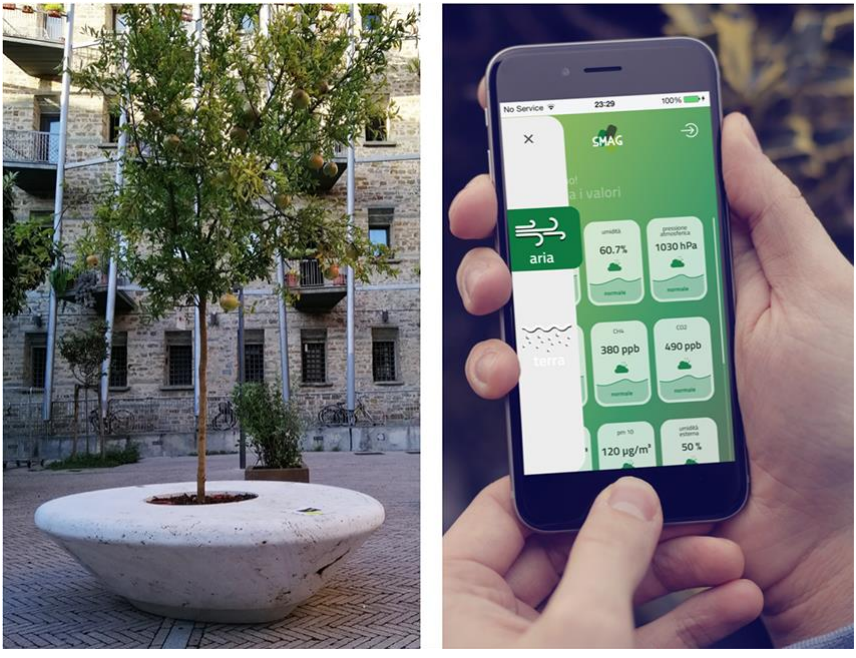

Figure 3. (left and right). On the left, the product of the Water Value collection; on the right, a screenshot of the SMAG system control application

Figure 4 - In figure no. 4 is shown the Litus system of seats and pots

Figure 5 (left and right) - In figure no. 5, on the left, is shown the control unit position in Litus collection; on the right a detail of the jar positioned into the Litus vase

It can therefore be said that the Smart Garden is, in essence, a garden that uses resources (water, energy, fertilizers, etc ...) and information (soil parameters, air parameters) in a good way, making use of ICT technologies and the possibility of monitoring capillary and in real time of the variables involved.

Figure 6 - In figure no. 6, is shown the Seven Dwarfs collection

4. Conclusion

The aim of the project was the creation of a system of intelligent objects capable of relating to the various actors who interact with the system: on the one hand with the gardener for aspects concerning health and maintenance of greenery; on the other with people, from an emotional / experiential point of view, with particular reference to the concepts of wellness and health.

The presented project could be defined as a behavior design project, that is, as a project aimed at conveying new behavior paradigms. The system designed monitors air quality and collects rainwater - sensitizing the user on the importance of plants for the absorption of CO2 and on proper management of resources -, helps garden maintainers to keep plants alive thanks to the constant monitoring of soil moisture and weather conditions.

As Mara Rossi states "The added value of design consists in the ability to create new paradigms, capable of directing organizational structures towards the construction of new behavioral forms (in our case, behavior with the natural environment). And with this assumption that it is possible to interpret design as a tool that guides society towards paths characterized by unprecedented forms of 'intelligence' (Rossi, 2014). Rullani reinterprets the concept of intelligence by affirming that we can speak of

"fluid intelligence, that is, knowledge that is not incorporated in machines or in automatic codes, but that is in people's brains and in the sedimented knowledge of their relationships" (Rullani 2008 in Mometti 2014, p. 87). [translation by the author]

In this scenario, life is considered a fundamental and essential element of innovation on which the designer's ability to implement processes that generate social and cultural change intervenes, to weave new and complex forms of relationships.

From these affirmations we can believe that the project activity must be able to systematically interact different cultural, social, technological, territorial aspects in order to direct the project to collective well-being.

To build this new paradigm of behavior it is therefore necessary to build a dialogue, a bridge between the two systems involved, human life and plant life. It is therefore necessary to guide a cultural change aimed at building an 'interspecies empathy'.

"Empathy defines an active involvement, that is, the willingness on the part of the observer to become part of the experience of the other and to share the emotions triggered by it" (Rifkin 2010, in Mometti 2014 p. 89). [translation by the author]

As Mometti argues (idem) regarding empathy between individuals belonging to the same species, these principles already exist and are scientifically demonstrated by the discovery of mirror neurons. But what happens when it is necessary to build empathic relationships between different species?

If empathy uses listening and analysis of accurate social feedback as a way of knowing the other, the role of the designer is also to build these feedbacks through the use of ICT in order to activate innovative processes capable of trigger social-behavioral transformations. In a world where we are destined to produce entropy, the project, taking up Morin's concepts (2015, see note 2) must be able to establish negentropic processes also of a social, cultural and behavioral type in order to re-establish a dialogical relationship with the natural world.

The boundary between the real world and the virtual world appears increasingly blurred and what we are experiencing can be defined as a real hybrid world between the materiality of the products, the immateriality of technology and the still unexplored world of science. Design is responsible for keeping these realities together in a scenario that is no longer that of the form of products but that of the form of relationships and, as Di Lucchio (2018, p. 5) argues, the development of new behaviors.

As Stefano Mancuso says:

“So this is our home: an area of 510 million square kilometers; enclosed in a volume that, roughly, ranges from 10,000 m below sea level to 10,000 above it; 20 total km that enclose the only place in the universe - as far as we are concerned - within which life exists" (Mancuso 2018, p. 15). [translation by the author]

A house, however, very small and fragile if we think that the Sun, which provides us with life, is over 1,300,000 times larger. However, this 'home' of ours is the only place in the universe known so far that has developed life. As Mancuso (2018, idem) states, therefore, it is not dimensions, but life that makes our planet special.

This is therefore the premise from which the designer should start: to design in order to protect the uniqueness - in diversity - of the earth, to guarantee the preservation of life.

Notes

[1] the text was conceived and structured by the three authors. However paragraphs "Abstract", no. 1"Introduction" and no. 4"Conclusion" are attributed to Marco Marseglia; no. 2 "Natural forms to emulate" and no. 3.1 "Interdependence between man and plant. a mutualistic relationship to be rebuilt" are attributed to Francesco Cantini; no. 3.2 "SMAG Project (SMArt Garden)" is attributed to Alessio Tanzini.

[2] Negentropy is not simply the opposite of entropy (negative entropy), the two terms, although constituting the positive and negative character of the same magnitude, correspond to antagonistic processes from the point of view of the organization. Entropy is disorganization and degenerescence, negentropy is reorganization, regeneration, development and complexification. Each negentropic self-producing process expels entropy as a byproduct of its activity and inscribes the complexity that is proper to it in the ring: disorder-interaction-order thanks to organization.

About the Authors:

Marco Marseglia Designer, PhD in Design, Temporary Researcher; his doctoral research has covered design flow and methods and tools for sustainable design. He has been part of the research group of the Design Laboratory for Sustainability (DIDALABS) since 2012, where he deals with product and life cycle design. Design 1 and Product Design teacher.

Francesco Cantini Designer, Design PhD Student, research fellow ; he research on the intersection between material design and materials science. Actually he has been part of the research group of the Design Laboratory for Sustainability (DIDALABS) since 2018 where he deals with regenerative design.

Alessio Tanzini Research fellow, with skills in product design and applications of enabling technologies (Additive Manufacturing, integration of sensors and actuators, etc.), for two years has been involved in research on issues related to environmental sustainability and sociocultural innovation at the Design Laboratory for Sustainability (DIDALABS).

Acknowledgements: We thank the Design Laboratory for Sustainability, in particular Manfredi Sottani and Marika Costa for the development of the application; a special thanks to the scientific director of the laboratory Prof. Giuseppe Lotti; the students of the Master's Degree course in Design and in particular Alessandra Galli, Jonathan Lagrimino, Mirko Romanelli, Giacomo Da Re; All the research team, Arredo di Pietra, Up Group, Nuvap and the Department of Agricultural Sciences and Technologies (UNIFI).

Abstract | Today, we are exposed to several thousands of chemicals via e.g. our living environment, cosmetics, textiles, clothing, drugs, and food. Most of the chemicals used in the textile and clothing production are harmful or dangerous to humans and nature. Harmful synthetic chemicals are applied in textiles especially during the finishing procedures e.g. to prevent mold growth in textiles. Natural, non-toxic substances used in textiles and clothing, are needed. F.BAD-project is an innovative combination of natural sciences, technology and textile design. Material applications of natural materials and non-toxic plant-based active ingredients will be combined with textiles. The promising preforms will be conceived and prototyped to combine organic active ingredients and materials solutions. The research generates information applicable in global context: antimicrobial activity, especially antifungal activity, insect repellent properties, and UV-shielding and/or color anti-fading properties in textiles.

KEYWORDS | HARMFUL CHEMICALS, SAFE PLANT-DERIVED SUBSTANCES, INTERDISCIPLINARY RESEARCH, BUSINESS ACTIONS

1. No more whining – natural smart textile

What is one part of your body where you most definitely do not want a mosquito bite? What mosquito repellent has the nicest scent? What kind of textile would keep mosquitos away? Answers to these questions and more are collected at mosquito-themed activity stations in the Future Bio Arctic Design (F.BAD) project.

- The project develops a natural, toxin-free and long-lasting textile to repel mosquitos. At activity stations, potential users of the textile can participate in its design process.
- Tests on different plants, active compounds and materials and results from mosquito-themed activity stations provide Lapland-based companies with the latest information from the textile industry.

This is a joint effort of the University of Lapland, Lapland University of Applied Sciences, and the Natural Resources Institute Finland (Luke). The working group represents a combination of art and sciences, with researchers from the textile and clothing industries, agrologists, chemists and material engineers working side by side.

At the innovative and interactive *No more whining (Nyt loppui ininä)* exhibition and at the mosquito-themed activity stations, people can watch and listen to interesting information about F.BAD research, design processes, and the life of mosquitoes. The aim of the mosquito-themed activity stations is to reach as many people as possible. This means that exhibition visitors have the opportunity to participate in research and design processes, and in the use of research results. The first mosquito-themed activity stations were held during the Helsinki Design week as a two-day event at the Helsinki Railway Square (5 and 6 September 2019). Following the *No more whining (Nyt loppui ininä)* exhibition held at Galleria Kopio, the next activity stations will be arranged during the northernmost design week in the world in Rovaniemi (Arctic Design Week, 16-22 March 2020). Results obtained from the activity stations will be taken into consideration during the final analysis of the project in the autumn of 2020.

The aim of the F.BAD project is to find replacement compounds for harmful and hazardous chemicals used in the textile industry from Lapland's nature, for example, to produce mosquito repellents and anti-mould agents, and to build a safe and natural smart textile from natural materials offered by Lapland, with active plant compounds included. Different methods and alternate materials will be tested to build the best possible smart textile. Alternate materials will also be tested with textile and clothing companies from Lapland, and they will be provided with an opportunity to use the Jacquard weaving method used by Finnish textile manufacturers. The Faculty of Art and Design at the University of Lapland has the only machinery intended for the design and weaving of Jacquard fabric in Lapland.

2. Mosquito-themed activity stations for multiple senses

Mosquito-themed activity stations are based on experiences provided for multiple senses. Visitors can test their sense of smell, vision, and touch. Even though the samples cannot be tasted (sense of taste) or the mosquito whine does not irritate visitors (sense of hearing) at the exhibition, natural raw materials and woven natural fabrics carry visitors to the atmosphere of a bilberry forest. Then again, not many of us think that, when we are walking around in a forest, we are also in close contact with the world's deadliest animal. More than 2,500 mosquito species are spread all over the world, apart from the Antarctic, and some three million people die of infectious diseases transmitted by mosquitoes every year. (World Health Organization (2013).

At the first activity station, visitors must attach a red F.BAD mosquito sticker to that part of the body that should most definitely be protected against mosquitoes. We all have been bitten by mosquitoes. Although different people react differently to stings and bites, and a broad range of products for insect stings and bites are available on the market, nearly all people are sensitive to mosquito bites. Mosquitoes can smell the lactic acid and carbon dioxide we produce from a distance of up to a hundred metres (Dekker, Geier & Cardé, 2005). If you do not want to be the number one target of mosquitoes, stay calm. However, many of us swing the air and jump around to get rid of mosquitoes, creating just the opposite effect. Could natural compounds and fibres (from plants and trees) sought in the F.BAD project replace some or all of the currently used harmful and hazardous chemicals?

The F.BAD project offers significant opportunities to use plant extracts and fibres as mosquito repellents and anti-mould agents. At the second activity station, visitors can smell different powdery products made from marsh Labrador tea, common nettle and tannins separated from spruce bark, and select the nicest scent for a mosquito repellent. The task is made more difficult by adding a commercial chemically manufactured mosquito repellent to the group. How many will select a natural repellent extracted from Lapland-based plants instead of the commercial product? Each scent has a F.BAD sticker of a distinctive colour (violet, green, orange and turquoise). Visitors need to attach a selected sticker to a cardboard figure located in the exhibition space to indicate the part of the body for which the selected scent would be the most suitable (Bog Myrtle, 2019; Labrador Tea, 2020; Nettle, 2019).

3. Mosquito repellent textile

At the third activity station, visitors are asked to draw or write their ideas of an ideal mosquito repellent textile. The aim is to gather information about how the project's results could be used later (Warmfamily Safari Patio Curtains […] ,2019); Zebra-striped jumpsuit, 2020; Zebra Wild Sun […], 2019).

There is already a range of mosquito and insect repellent textiles. (Menghe & Xin, 2018) However, they include permethrin, which is highly hazardous to the environment, fish and certain mammals. (Oxborough, 2015). Thousands of chemicals are used in the treatment of textile fabrics alone, most of which are harmful both to people and the environment. (Menghe & Xin, 2018; Oxborough, 2015; Thite & Gudiyawar, 2015) What is more, we are exposed to chemicals every day through medicines, cosmetics, nutrition and the environment. As yet, we do not have a sufficient amount of reliable information about the long-term and joint effects of these compounds. (Koniecki, Wang, Moody & Jiping 2011)

Not all chemicals used in textile manufacturing are necessary, and not all chemicals are transmitted into the organ system. Then again, it may be difficult for consumers to protect themselves if manufacturers use hazardous chemicals in their textile manufacturing processes. (Menghe & Xin, 2018) Chemicals make textiles more comfortable to wear and more long-lasting when used, for example, in different finishing methods. In addition to different cleaning processes, fabrics undergo anti-mould and anti-static treatments, biological protection and different treatment processes to make them easier to iron, prevent them from wrinkling, make them softer and make them more fireproof, water-repellent and durable. (Menghe & Xin, 2018; Marechal, Križanec, Vajnhandl &Valh, 2012) During long transport and storage periods, textiles are also exposed to microbes, mould, fungi and various insects. As a result, textiles are biologically protected, for example, by using organic chlorine, tin and chromium compounds that are very harmful to people and the environment. (Marechal et al., 2012)

The European Chemicals Agency maintains a list of chemicals hazardous to health that are used in textiles. For example, the Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH) regulation sets strict requirements for the textile industry, as it requires that the safety of all chemicals be ensured, transparency be increased, and eco-friendlier innovation be made (Koniecki et al., 2011; Marechal et al., 2012).

The F.BAD project focuses on toxic-free methods and compounds. At the same time, new material and product ideas will be prepared for the textile and clothing industry in the arctic region, and research, competence and innovation clusters will be developed in Lapland on the basis of the region's strengths. Tests of different plants, active compounds and materials, and results from mosquito-themed activity stations provide Lapland-based companies with the latest information from the textile industry. Lapland -based textile and clothing companies are also able to test the results of material research during Jacquard weaving workshops at the University of Lapland and Annala Oy. The F.BAD project considers, among other questions, whether a natural mosquito repellent smart textile prototype can be built by combining natural materials and scents from Lapland and the weave design enabled by the Jacquard technology. (Design, Weave, Show, CAD/CAM Software […], 2019; Fernström, 2012)

The goal of the F.BAD project is to develop options to repel mosquitoes without any health-related risks, and its research applications also include different mosquito repellent equipment. Covering all parts of the body helps to reduce the number of mosquito bites. However, mosquitoes can also bite through clothing. The colour of clothing is an important factor. Dark colours are known to attract mosquitoes, while light clothes keep mosquitoes better away.

Commercial mosquito clothes are worn over other pieces of clothing, including hats, overcoats and trousers made from mesh materials. There are also mesh gloves and mittens and sock-like footwear available. This means that it is possible to cover the entire body with mesh fabrics to prevent mosquito bites. What is characteristic about mosquito repellent clothes is that they are usually dark green or feature the military camouflage pattern. From this, it can be concluded that the mosquito repellent clothing imitate natural colours and camouflage the wearer in nature, but not repel mosquitoes.

As a result, the F.BAD project focuses on the best colours and patterns to be used in mosquito repellent clothes and materials. It is widely known that mosquitoes select their targets through three phases: their sense of smell drives them towards carbon dioxide, their sense of vision helps to approach their target and, finally, they pinpoint their target on the basis of body heat. Textile pattern design could focus more on the way mosquitoes navigate to their targets.

What kinds of optical illusions could be used or developed to this end? Optical illusions have been used in clothing in different ways at different times. Optical art (op art) was a significant international art phenomenon, for example, in London, Paris and New York in the 1960s. It was based on visual arts, while many fashion designers applied its visual side to patterns and woven fabrics. Clothes were simple in design, but their bold colours and textile patterns made them sort of move on their own. In recent years, interest in optical illusions has increased. Experimental designs have been demonstrated at fashion shows in different parts of the world. Fashion shops offer various textiles, clothes and accessories with different animal patterns, such as panther, leopard, tiger, zebra, and giraffe patterns. (Hasbullah, Westland & Cheung, 2016; Elshafei, 2015; Ridgway, 2014).

Although zebra and leopard stripes seem to stand out easily from their surroundings, they act as a protective colour, distorting and blurring the predator's vision and, therefore, helping animals to hide and camouflage in their environment. Zebra stripes are known to protect zebras from bloodsucking insects. This knowledge has been used when studying the behaviour of horse-flies. A striped blanket was put on a few horses. Researchers discovered that zebra stripes interfere with the fairly weak vision of insects so that it became more difficult to land on the animal, which in turn reduced the ability of horse-flies to bite animals and suck their blood (Caro et al., 2019; Caro et al., 2014; Horváth et al., 2019; Klein 2019; Melin, Kline & Hiramatsu, 2016).

Could a scented moiré pattern act as a mosquito repellent textile in the future? Usually, the moiré pattern is never seen out in the wild, while it is fairly common in an urban environment, for example, in the folds of window curtains or worn by a TV presenter. Moiré is an interference pattern made by overlaying a specific type of woven fabric or lines on a printed fabric to produce a new pattern.

The moiré pattern is usually regarded as an unwanted pattern or an error that needs to be fixed. Recently, it has been added to experimental and commercial clothing, and also to horse blankets. In the F.BAD project, the study of textile pattern design focuses on the production of a moiré pattern by both stacking transparent material layers one on top of the other and by using colourful printed textile patterns. Both ways can be used to produce new textile patterns and illusions of movement. The goal is to develop the material so that it can be used as a visual mosquito repellent.

The cleanliness, health and safety of Lapland´s nature are significant values that are used in marketing and branding in many sectors. Arctic quality has also been studied scientifically in the fields of natural resources and tourism, as well as in different services. To develop, Lapland needs innovation and new technologies. This is only possible with true cooperation between people from different fields – without any whining. (Bog Myrtle 2019; Labrador Tea 2020; Nettle 2019)

Paving the way to post-digital smart materials. Experiments on human perceptions of a bio-inspired cellulose-based responsive interface.

Stefano Parisi*[a], Markus Holzbach[b], Valentina Rognoli [a]

[a]Politecnico di Milano, Design Department
[b]Offenbach University of Art and Design
*stefano.parisi@polimi.it

Abstract | The paper aims to frame the emerging scenario of hybrid interactive systems, and pave the way for post-digital interactive materials, proposing organic material interactive interfaces as a potential alternative to digital and electronic-based ones. Supported by the theoretical background and related works, a case study developed by one of the authors is presented: a cellulose-based interactive interface where the material itself work as a sensor and an actuator. This new generation of smart materials enables and implies novel experiential patterns to observe and discuss. An exploratory workshop on this novel typology of material interface carried out by one of the authors is then described addressing the critical issues of users' perception and appreciation. The methodology of the activity is based on quantitative and qualitative data collection through a questionnaire made of scale questions and open-ended questions, plus direct observation and discussions with the participants. The activity integrates the lens of Materials Experience, in order to overcome the missing understanding of the experiences enabled and implied by this interface. Prominent findings unfold the relationship between temporal and static expressions. Finally, biomimicry arises as an approach to transfer the feeling of nature and to create more intuitive interaction.

KEYWORDS | MATERIALS EXPERIENCE, BIOMIMICRY, CELLULOSE-BASED INTERFACE, HYBRID MATERIAL SYSTEMS, RESPONSIVE MATERIALS

1. Introduction

In the research and practice around material design, different post-digital scenarios are currently emerging. Computers, as we know them today, will disappear into things that are, first and foremost, something else (Negroponte, 1998).

The paper aims to frame the emerging scenario of hybrid interactive systems and pave the way for post-digital interactive materials, proposing organic material interactive interfaces as a potential alternative to digital and electronic-based ones. Supported by the theoretical background and related works, a case study developed by one of the authors is presented: Transformative Paper (Holzbach, 2015a), a cellulose-based interactive interface where the material itself works as a sensor and an actuator.

Comparing to traditional electronic-based smart materials, this newer generation of hybrid interactive materials enables and implies novel experiences and opportunities of combining dynamism and authenticity. The experiential patterns mediated by the formal and behavioral qualities of such materials need to be explored and discussed. Therefore, an exploratory workshop on this novel typology of material interface carried out by one of the authors and involving a selected group of participants is then described addressing the critical issues of users' perception and appreciation. From this activity, promising preliminary results on people perception emerge and set the base for further research actions.

2. Theoretical background and State of the Art

2.1. Hybrid Interactive Systems

Today, besides objects equipped with artificial "intelligence," materials themselves may be informed and rewritten by micro-scaling digital or procedural activities. Micro-scaling can lead to the hidden information of traditional materials and everyday objects surrounding us. This results in an aesthetic and functional augmentation of existing materials that infuse materials of "living" or "intelligent" qualities. At this stage, new properties are usually constructively linked to the material on a macroscale level and in a traditional way – for example, through layering.

This brings to the emergence of materials with responsive behaviors that can detect, process, and manifest data. "Smart materials" is a relatively new expression used to identify materials that have changeable properties, in opposition to traditional materials that are latent (Ritter, 2006). They can change some features like shape or color in response to physical or chemical influence from the environment or the users' body.

It is often possible to combine several materials with smart properties together to create *Smart Material Composites* (Barati et al., 2019), and to combine actuating, sensing and controlling electronics into *Smart Composite Material Systems* (Kelly, 2017) in order to

increase the smart qualities of the final product. The combination of organic and inorganic components, including micro components such as electronics leads to the definition of *Hybrid Materials* (Saveleva et al., 2019; Ritter, 2006). As a result, *Hybrid Material Systems* (Parisi & Ferraro, 2021, p. 127) are defined as “material-based systems encompassing different components such as inactive materials, smart material components, sensors, actuators, computational layers”.

Due to the increasing miniaturization of technologies, the seamless integration of sensors and actuators into materials have been theorized and envisioned in the notion of *Augmented Materials* (Razzaque et al., 2013*), Expanded Matter* (Brownell, 2014), *Computational Composites* (Vallgårda & Sokoler, 2010), *Material programming* (Vallgårda et al., 2017), and *Interactive, Connected, and Smart (ICS) materials* (Ferrara et al., 2018; Rognoli & Parisi, 2021).

While at the beginning the first wave of digitality affected drawing and visualization tools for design, then digital production tools and the process chains derived from them followed. The resulting connection of the digital with the physical – or the material – results in directly derivable hybrid structures with their own hybrid property profiles. This results in a formal and functional augmentation of existing materials, that infuse materials of "living" or "intelligent" qualities. Hybrid materials are multi-layered and heterogeneously informed. As a result, materials are becoming increasingly informative and intuitive.

Some hybrid Interactive systems are designed by using designed Materials. This leads to the question of whether the discussion about constructions that are suitable for the material or design which is suitable for the material is outdated or not. Today, materials are developed to perform a task. The question of materiality arises as a central decision and development at the beginning of a design task and not as a selection from existing materials at the end of the project (Parisi et al., 2020). Material-oriented design is increasingly turning into “design with designed materials” (Holzbach, 2015a).

2.2. Material Authenticity

Many of today's material solutions integrate new technologies and components, and their scale and complexity no longer allow conclusions to be drawn about their performance or function. This is also the ambivalence of the material solutions presented here in the paper. In the articulation of these new and hybrid material solutions lies the important cultural mission of material design (Holzbach, 2015a)**.** In most cases, designers look for a suitable material for their design or design the product with a specific material in mind. This "material authenticity" – i.e. what a material intrinsically is and naturally does – seems to be overcome.

Today, the world of materials, substances, and semi-finished products meets digital design and production methods, changing the conventional idea of material “authenticity”. This fundamentally changes the way design concepts are conceived and leads to entirely new

ways of thinking. Today, materials are rather developed for their task. "Materials with sensitive, smart, or gradually varying properties lead to new and complex design concepts. This opens up new possibilities at the level of concept, form, structure, and surface. The path from static to dynamic, process-oriented properties is thus smoothed." (Holzbach, 2014a, p. 69). As Sabine Kraft writes:

> "The relationship between form and material has become as diverse as it is ambiguous. A recourse to clear rules and specifications as to what can be conceived and constructed in which material and how, and which aesthetic message would be transported by this, is hardly possible anymore - if it ever existed." (Kraft, 2004, p.24)

"Informed" or "augmented" materials with sensitive or smart properties, thus lead to an increasing blending of different contexts. Mixed forms emerge that no longer allow a clear separation. As a being of our time, the increasing intertwining of the most diverse areas of life and knowledge can be seen. New material and design concepts are also acting in this context, resulting from the overlapping of digital and analog, nature and artifact. It is the interdisciplinary process that see and define material, form and construction as a holistic unit. Where is the border between real and fake, natural, and artificial?

What meaning can the term material authenticity still have in our digitized world? The digital, in particular, is predestined to connect different sensory levels. In the digitalized world surrounding us, and especially in contemporary art and cultural positions, such border crossers in the intersection of Art and Science or Design and Technology are of increasing importance. To what extent do nature and the artificially created interact to create a new form with its own hybrid characteristics? Where does something begin, and where does something end?

A permanent comparison of information and materialization takes place. In addition to the digital programming of materials, specific material parameters can continue to be embedded in the digital models. "It is precisely the dialogue of the "real" material with the "virtual" and "dematerialized" digital world that leads to new formal and functional impulses and contexts" (Holzbach, 2014b). The virtual and the real are interwoven and thus lead to new hybrid property and design profiles. Analog and digital material concepts and their hybrids become the carriers of information. Materials become informative or even intuitive, enter into a dialogue with their environment and thus have new functions of meaning. The material acts at the interface of the digitalized and real world. The traditional thought pattern of "material-authentic design" is broken through the link between digitization and materialization. Here a substitution of important digital components in favor of natural materials is taking place. The material itself takes over essential tasks and increasingly seems to have intrinsic qualities.

2.3. Post-digital Interactive Materials

In a future perspective, the possibility to substitute traditional electronic components, even with bio-based or bio-inspired ones, is not remote. In the first German edition of Domus,

Mateo Kries (2013), director of the Vitra Design Museum, writes: “Museums today must treat design as what it is – as a cross-sectional discipline between art, science, and technology”.

Nature, with its structures and constructive laws, often serves as a valuable source of inspiration for material design as well as new technologies, through biomimicry (Salvia et al., 2009) and the cooperation of digital manufacturing (Langella, 2007). Recent definitions of *Bio-Smart materials* (Lucibello et al., 2018; Ferrara et al., 2019) and *Bio-Synergistic materials* (Parisi & Shetty, 2020) elaborate the mechanical and biological response to stimuli of natural-based materials as a medium of smart behaviors.

One challenge for the development of hybrid material systems is the one of sustainability, in particular the use of non-toxic, renewable, and biodegradable materials. The integration with biodegradable materials and fibers may allow the separation of components. This is the case of interactive wearables and objects using mycelium as a support and structure for electronics (Lazaro Vasquez & Vega, 2019), or the use of bioplastics for robotics (Kretzer & Mostafavi, 2021) or transient electronics (Tao et al., 2012). An example of design experimentation is a conductive bio-skin made by growing bacterial cellulose with conductive compounds by designer Giulia Tomasello (Fig. 1).

Figure 1. Conductive Bio Skin experiments by Giulia Tomasello.

However, the use of materials with changing properties is not an invention of modern times, and those responsive behaviors can be found in nature (Ritter, 2006). Examples of organic materials and micro-organisms enabling aesthetic and functional dynamic responses in fashion and product design can be found in the literature. In this respect, biological organisms can also be used as biosensors and bio-actuators to replace synthetic ones.

This is the examples of BioLogic (Yao et al., 2015), a textile which uses the mechanical behavior of Natto bacteria masses deposited on portions of textile to respond to moisture (Fig. 2). The bacteria’s body enlarges with humidity allowing the textile to change shape. Other examples of biosensors are Organic Primitives (Kan et al., 2017), pH-reactive organic materials used for sensing, actuation, and interaction, (Fig. 3) or the use of bioluminescent organisms for performing light-emitting behaviors.

Figure 2. BioLogic by MIT Media Lab (Lining Yao), 2015 (photo by Rob Chron).

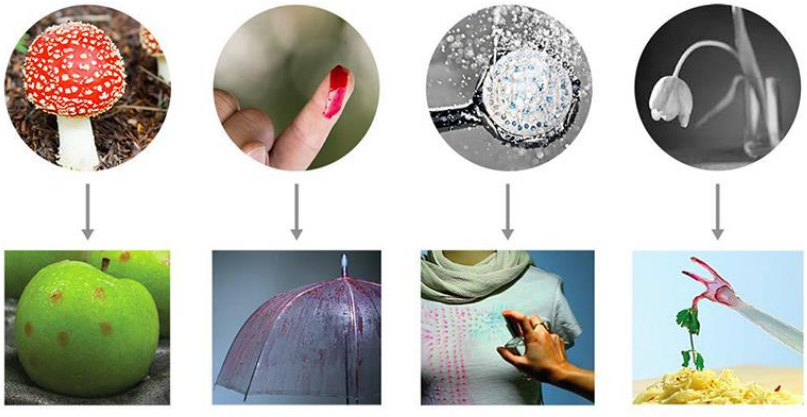

Figure 3. Organic Primitives by MIT Mediated Matter Lab (Viirj Kan).

Researchers and designers are exploring the smart behaviors of traditional materials supported by digital manufacturing and parametric design, such as organic pulp-based surfaces and fibers reacting to moisture. Programmable knitting (Scott, 2018) tested the shape-shifting moisture-responding anisotropic behavior of pulp-based fibers woven into

textiles to determine the geometry related to each deformation and integrate it in the design process by using parametric design (Fig. 4).

Figure 4. Programmable Knitting, by Jane Scott, 2018. On the left: growing medium profile. On the right: Shear, after actuation (photo by Cristina Schek).

This newer generation of hybrid and post-digital materials also shows the reactive properties of the natural world. However, the post-digital and bio-mimetic materials show authentic properties connected intrinsically to the material. The combination or description of new properties via micro-scale digital or procedural components is perceived as an embedded "intrinsic" property and as inherent to the respective material. The properties of the living are conveyed even more strongly in these materials, since the material apparently reacts automatically to its environment. The hidden individual components lead to the suggestion of existing formal and functional properties in the material itself. These are per se not present in the actual material or artifact, but rather result from the hidden current and operating properties.

The traditional nomenclature of design and its semantics is at this point undermined. The encoded and rewritten material can no longer be decoded with a classical sign function or described with questions about "material authenticity". The product language, which acts out of its symbolic or symbolic nature, can therefore no longer be used as an unrestrictedly effective means. Instead, the object is "intuitively" or even "not" accessible. Our existing, object-like environment is able to communicate, but no longer communicates this to us - in the sense of a classic sign function - as it used to.

3. Case Study: Transformative Paper

A case study of post-digital interactive material developed was developed by one of the authors as a result of a student's project and is presented in this section. Similar to Programmable Knitted by Jane Scott (2018), the authors' case study is a cellulose-based interactive interface in which the material itself works as a sensor and an actuator. It is a shape-changing multi-layered surface made of paper combined with a plastic layer and cut in

small bio-inspired segments reacting to short-term environmental conditions, as a combination of the properties of the material and the designed shape. Depending on the air humidity, the paper structure morphing without electronically based sensors into various states (Holzbach, 2015b).

The project Transformative Paper (Fig. 5) was developed in a collaboration between the Institute for Materialdesign at the Offenbach University of Art and Design and the company BMW. A whole series of different concepts of responding surfaces was created under the guiding theme "Intuitive Brain." These surfaces were developed by students by using different interpretations and perspectives around the theme, which convey the “intuitive” meaning in different ways.

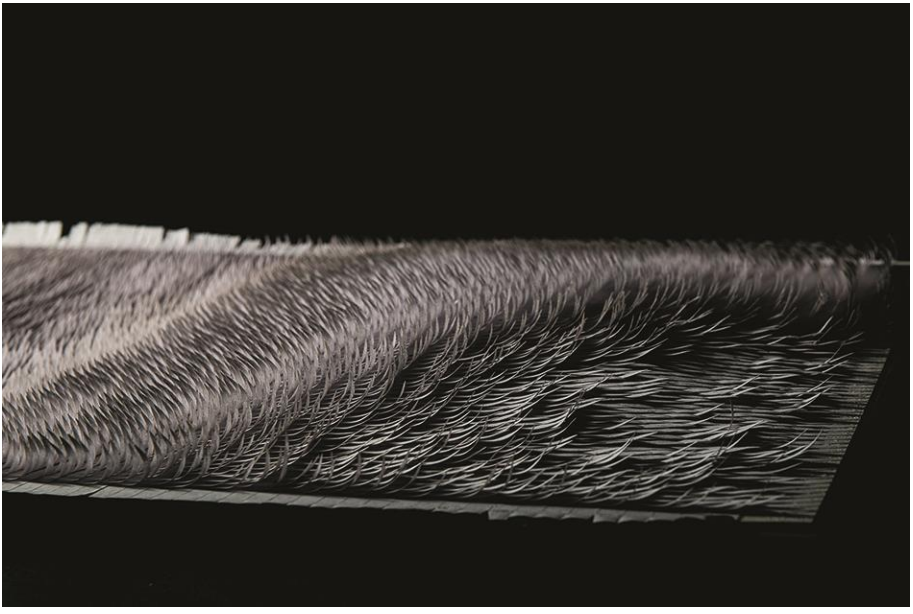

Figure 5. Transformative Paper by Florian Hundt, a result of the cooperation "Intuitive brain" between Prof. Dr.-Ing. Markus Holzbach, Institute for Materialdesign IMD, HfG Offenbach and BMW AG, 2015. The interactive surface uses the anisotropic condition of papers, in combination with a plastic film, to perform a dynamic behavior when triggered by moisture.

In this particular case, the responding capability of the project is based on the notion of anisotropy: a condition in which specific material properties can vary depending on the direction. This also applies to wood and especially wood veneer with its fiber-based structure. In the first conceptual, preliminary stage, the interaction of the veneer wood and its anisotropy with the macrostructure consisting of different fractals has already been

established. Depending on the moisture distribution to the used wood species, and according to the orientation of the veneer wood, different forms can be realized. For instance, a one-sided moisture supply leads to corresponding swelling processes in the wood. This leads to tensions and deformations in the wood.

This behavior is reversible, and the process is reversed with increasing drying. The material and thus also the structure resume their original form. Controlled by the alignment of the veneer modules, "intelligent" structures become conceivable, which react to both the absolute humidity and the distribution of moisture in the room and which can fulfill specific practical and aesthetic functions through their three-dimensional deformation. The reactive surface serves as both a sensor and an actuator (Fig. 6).

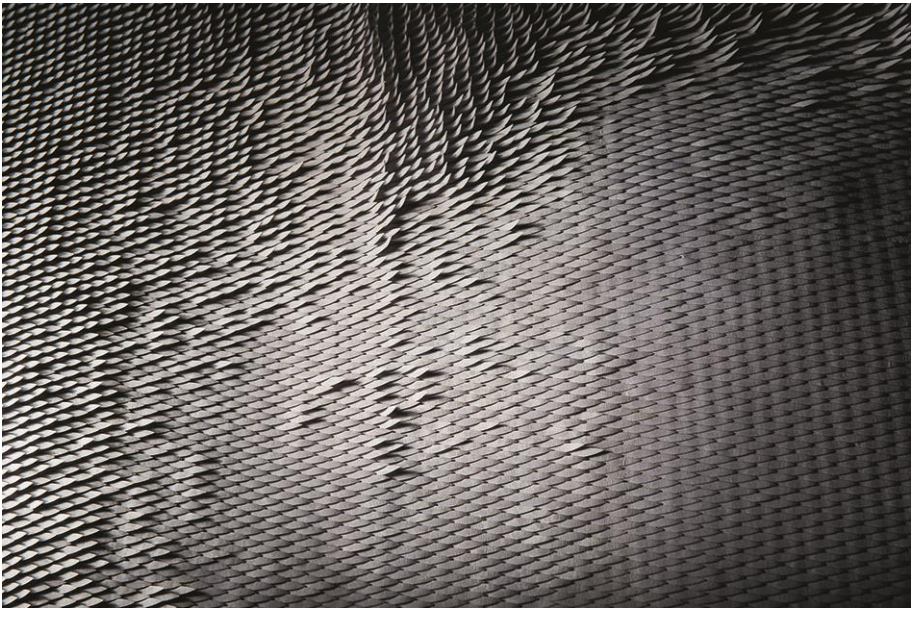

Figure 6. Transformative Paper by Florian Hundt, a result of the cooperation "Intuitive brain" between Prof. Dr.-Ing. Markus Holzbach, Institute for Materialdesign IMD, HfG Offenbach and BMW AG, 2015. A detail of the interactive surface.

Basing on this logic, the behavior of anisotropy should be exploited in further development. Up to now, wood has been the most commonly used raw material in paper processing. Since paper is made directly from the wood, it has the same swelling behavior and also the anisotropic properties of wood. Conventionally, these effects, which result from the anisotropy of the starting material, are undesirable, especially with machine-made paper and in a wide range of areas of application. On the contrary, isotropic properties are desired, i.e., materials whose property profiles are the same in different directions and thus

homogeneous. However, In the development of the project, a series of tests were performed in order to investigate and verify the anisotropic behavior of wood. For example, according to the type of wood, growth conditions, and other variables, different properties are obtained in different growth directions. Strengths, swelling behavior, and deformation behavior can be predicted quite precisely. In particular, in the scope of the work presented here, the effects resulting from anisotropy are of particular advantage.

After all, in a post-digital scenario, the adaptive and interactive qualities of materials are expected to be developed from an authentic and inherit – "intuitive" – material intelligence and without the addition of a digital component. Thus, specific deformation properties can be introduced into desired areas of reactive surfaces in a very targeted manner. The individual fractals are integrated into the overall surface and positioned individually, quasi tailor-made.

The main goal of the presented work "Transformative Paper" was formulated as the independent response of an interactive automotive skin to the influence of the weather and especially to the interaction with rain. The developed reactive skin reacts automatically and is intuitively able to adapt to the weather. If one makes use of the anisotropic properties of the paper and combines the paper with other materials, new areas of application and contexts can be opened up. In this case study, the paper layer was constructively combined with another plastic film in a multilayer construction. The resulting multilayer construction reacts continuously to environmental influences. Depending on the humidity, the paper structure is transformed into different states. This results in a gesture that can appear so subtle when humidity is low that the transformation is not evident at first glance. The transformation takes place more evident when the surface is exposed to moderate moisture and heavy rain. If the structure is dried, the individual segments will stand up. When wet, the structure closes entirely automatically and without digital control or regulation (Holzbach, 2015a).

4. Exploratory workshop on users' perception

A challenge for design research is identifying meaningful ways to design with and for materials like this. They imply complex and novel experiences that designers need to comprehend and implement to foster people's appreciation and acceptance (Parisi & Shetty, 2020).

An exploratory workshop on this novel typology of material interface involving a limited number of selected participants was carried out by one of the authors and is here described addressing the critical issues of users' perception and appreciation, and to overcome the missing understanding of the experiences enabled and implied by this interface. In particular, the object of the study is Transformative Paper, by the collaboration between the Institute for Materialdesign at the Offenbach University of Art and Design and the company BMW AG, the one broadly presented in the previous section of the paper. The study was

organized in the format of a workshop with users, aiming at unfolding qualitative patterns (Petrelli et al., 2016), using the lens of Materials Experience (Karana et al., 2015; Giaccardi & Karana, 2015). The setup, methodology, and results of the study are thoroughly described in this section.

4.1. Methodology

The activity was organized in the format of a small workshop of 1 hour and 30 minutes. The activity was performed at the School of Design of the Politecnico di Milano. The study involved 20 participants, including design students (13), practitioners, (4) and scholars (3), from 4 different countries, i.e., Italy (13), Portugal (5), Brasil (1), Perù (1).

The methodology of the activity is based on quantitative and qualitative data collection through a questionnaire made of scale questions and open-ended questions, plus direct observation by one of the authors and discussions with the participants. The activity was divided in four subsequent phases:

- exploration and analysis of the static form and expression of the material;
- exploration and analysis of the dynamic form and expression of the material;
- comparison with other dynamic materials, i.e., thermochromic painting, electroluminescent ink, shape-memory alloy spring, and oxidizing copper;
- participant's background, previous knowledge and final remark.

The lens used to observe and analyze the item is the one of Materials Experience. Each of the moment was introduced by small presentations by the author, with the support of projected slides, including the introduction of grounding theoretical notions with examples and showcasing of the samples. A coded envelope and four papers containing questions and scales related to each of the four phases, namely part A, part B, part C, and part D, were distributed during the execution of the activity to each participant as a compass to the activity and to collect data. After each moment, before explaining the following part and distributing the related paper, the author encourages a moment of discussion with the participant in order to unfold key issues in the scope of the research. The language use for the questionnaire, the execution of the activity, and the discussion was English. Participants were asked to fill the questionnaire and express their opinion in the discussion in English or in their mother language if that made them more comfortable. This was appreciated when allowed to provide more accurate and complex description of feelings and recalls in the participant's memory.

The questionnaire was set as follow:

Part A: the sample is shown in its static expression. A sensorial evaluation scale (Karana, 2009) was provided to support the evaluation of the samples.

- How would you describe the material?
- Which are the main sensorial qualities?

- Which emotions, feelings and memories does the material elicit in you? Why?
- Which adjectives/meanings would you use to describe the material? Why?
- How would you approach and interact with the material?
- How would you think it would change in time?

Part B: the sample is shown in its dynamic expression.

- How would you describe the behaviour of the material? What are the inputs? What are the outputs? What are the qualities of the behaviour?
- Which emotions, feeling and memories does the behaviour elicit in you? Why?
- Which adjective/meanings would you use to describe the behaviour? Why?
- Look at the previous paper (paper A): is the experience elicited by the material changed? What in particular? Think about the sensorial qualities, emotions, meanings, way of interacting or approaching the materials. Would you change the nickname of the material?

Part C: other materials showcasing dynamic behaviors are shown and compared.

- Describe the different experiences resulting from the materials and related behaviours. Use the questions in the previous page (paper B) as a guide for the description.
- Put the different experiences in order of preferences and explain why?

Part D: questions for demographic data (age, nationality, job), previous knowledge on the topic (Transformative Paper, Materials Experience, Smart and Interactive Materials), and optional comments are contained.

Paper questionnaires and audio recording of the activity were digitalized and transcribed by the author in tables. Comments and answers in mother language were translated by the author. Once transcribed, data were analyzed by the author in order to extract patterns, contradictions, and key considerations.

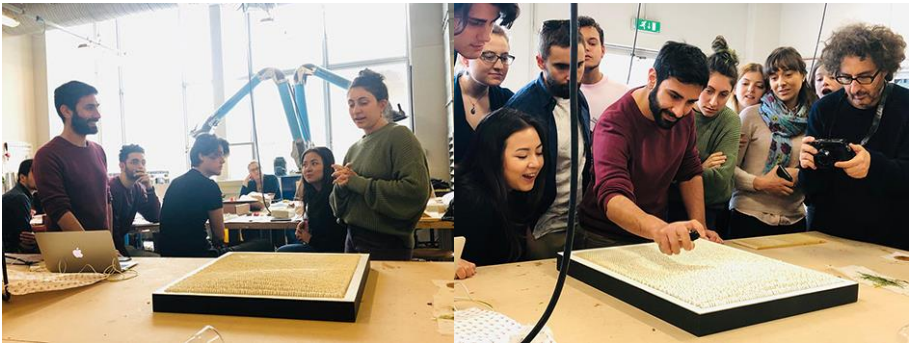

Figure 7. Two phases of the exploratory workshop, carried out by Stefano Parisi, Polimi, 2019.

4.2 Results and discussion

Among the results, prominent findings unfold the relationship between temporal and static expressions. For instance, slow bio-inspired responses and the principle of accordance between shape, material, and behavior evoke positive connections.

In particular, the behavior and dynamic expression influence the experience (Rognoli, 2015), modifying all the layers of experience. Some people had a positive reception to the materials, mainly related to the feeling of surprise and wonder, while to other the behavior itself was considered as aggressive. Slow behaviors are considered more evocative and emotional. Diffusely, the behavior was considered as natural and assimilated to vegetal elements. Thanks to the behavior the materials was considered as “alive.” This was considered positively. Some participants underline the fact that the material, in the static dimension, suggested how the material would move, by reminding a field of grass. This accordance appears to be key.

Biomimicry arises as an approach to transfer the feeling of nature and to create more intuitive interaction. Most of the participants are encouraged to interact with the material when static, while when reacting at first preferred to observe instead of touching.

In this case, the input (water) not only trigger the behavior (shape-changing), but changes the qualities of the material itself, making the materials wet and softer, which is perceived by participants as more fragile or comfortable. The natural transformation of the substrate with time (e.g. ageing) may interact with the reversible behavior.

Limitation of the activity is related to the diversity of samples provided, in terms of shape, applications, and details. In fact, while the main object of the study was considered by the participant as a designed material system with a high artistic value, the other samples used for the comparison – namely, thermochromic painting, electroluminescent ink, shape-memory alloy spring, and oxidizing copper – didn’t have the same complexity and were considered as material samples. Plus, among these material samples, some of them were designed for a specific application. In general, the items didn’t have common characteristics that would make the comparison more objective, i.e. size, thickness, colors, surface qualities such as texture, performance qualities such as flexibility. While Transformative Paper had a proper showcasing divided in two moments leading the participants to explore thoroughly its static and dynamic dimensions, the other samples used for the comparison didn’t have the same space for presentation and showcase. Another limit is represented by the small sample of participants involved and by their robust relation with the area of design and materials. Following studies may involve unskilled participant, unfamiliar to the topic.

5. Conclusions

Concluding, the paper presents the emerging scenario of hybrid interactive systems and paved the way for post-digital interactive materials. In particular the authors used a speculative approach to propose organic material interactive interfaces as a potential alternative to digital and electronic-based ones. Supported by the theoretical background and related works, the authors demonstrated the potential of this novel area of advanced materials, in particular the ones related to intuitiveness and authenticity of the interaction and communication between the users and material interfaces. Secondly, the challenge of sustainability is promoted by the use of organic and natural interactive components, instead of digital, chemical, and artificial ones. A case study developed by one of the authors is presented: a cellulose-based interactive interface where the material itself works as a sensor and an actuator. An exploratory workshop based on the notion of Materials Experience on this novel typology of material interface carried out by the authors validated the hypothesis of the beneficial impact of such materials in enhancing meaningful and positive experiences for the users. Not only, it triggers complex interplays between the behavior, the shape, and the material qualities opening up to original ways of designing and experiencing the artifact.

Although the exploratory workshop is conducted with a narrow, insular, and small number of participant and to date has not been repeated yet, it presents some interesting and promising insights to use as a base knowledge for further research actions. The methodology of the exploratory workshop can be considered as a pilot or prototype for a more in-depth user study.

The authors underline that the case study is analogic and does not use embedded technology and smart components to react. However, it is key to the study as an example of dynamic materials, in order to retrieve information to use not only for the development of post-digital interactive materials, but to extend to smart materials with embedded electronics, in order to reiterate positive experiences. Indeed, data obtained from the studies are intended to be applied to the design of hybrid material systems as part of a broader methodology.

About the Authors:

Stefano Parisi is a Research Fellow at the Department of Design, Politecnico di Milano. He investigates innovative knowledge transfer methods and tools for design students and practitioners about emerging materials – mainly smart and biomaterials – with an emphasis on materials experience.

Markus Holzbach is Professor at HfG Offenbach, since 2009. There, as qualified architect and materials and process engineer, he heads the IMD Institute for Materialdesign. The focus of his work is the role of the materials in the design process. Visiting Professor at Politecnico di Milano.

Valentina Rognoli is Associate Professor in the Department of Design, Politecnico di Milano. She is a pioneer in the field of materials experience and has internationally recognized expertise on the topic both in research and education. Since 2015, she jointly leads the Materials Experience Lab.

Acknowledgements: we thank all the people who participated to the exploratory workshop, first of all our students and colleagues. Markus Holzbach personally addresses his special thanks to BMW AG for the cooperation with the IMD Institute for Materialdesign at the University of Art and Design Offenbach and for their valuable support in the research project “Intuitive Brain.” Special thanks also go to Florian Hundt, who participated in the “Intuitive Brain” project as a student and made his work “Transformative Paper” available for this paper.

The flow of emotions in co-creation

Mariluz Soto[a]*, Caoimhe Isha Beaulé[a], Satu Miettinen[a]

[a]University of Lapland
*msoto@ulapland.fi

Abstract | Co-creation is a broadly used practise among service designers, as a workshop is an effective way to build new solutions or improvements together. The focus of this article is on the emotions arising before and during the co-creation workshop and a reflection on what influences them. The first purpose of this article is to deepen the understanding of emotions that emerge in the co-creation workshops that are commonly encountered by the different participants. The second purpose is to determine if there are other factors that influence the experience of co-creation. In this article, emotions are considered a human response—consciously or unconsciously—that connects human beings with their surroundings. This connection has an impact on people's emotions and determines their experience, attitude, behaviours and interactions in the workshop environment.

KEYWORDS | EMOTIONS, CO-CREATION, COMMUNITY, INTERACTION, HUMAN SURROUNDINGS

1. Introduction

Service design is a rapidly evolving field, both in research and in practice. One of its most common practices, co-creation, is also constantly evolving. According to Sanders and Stappers (2008), co-creation starts with two approaches: the first considering the user as an informant or expert of their own experience, and the second considering the user as a fundamental part of the creation process, that is, a partner. Over the years, both approaches have co-existed and matured. Indeed, a service design process is generally participative, and the methods and tools used often enhance collaboration (Sangiorgi & Prendiville, 2017). Nonetheless, human-centred approaches, prevalent both in design and in Western worldviews, have been criticised for their anthropocentricity (Acosta & Romeva, 2010), neglecting all other elements we (humans) interact with, although we are only one part of a larger ecosystem.

Surprisingly, although highly human-related, the emotional components of co-creative practices are often overlooked (Soto et al., 2020a) and even unacknowledged as essential elements to consider in these collaborative settings (Miettinen & Sarantou, 2019). Emotions have a significant impact on people's decisions, their perceptions and their relationship with their environment. The complexity of the projects could be addressed by designers, starting with the consideration of the people involved (Miettinen & Sarantou, 2019) and their ecosystems. A new way to understand emotions in the interaction between humans and non-humans environments could contribute to the development of better environments for co-creation and enhance participative experiences. Hence, this article asks the following question: What elements can influence the emotions experienced by participants in a co-creation workshop? This paper has a practical perspective that is based on the findings from data collected between 2018 and 2020 as part of a doctoral dissertation on the emotional skills of service designers in co-creation practices (Soto, 2021). First, data were collected in a Master level course in service design taught in Finland (NN:9 students). Second, data were collected during three service design sprints organised in Sweden, Finland and Estonia (NN:44), and finally, an online open-ended questionnaire was administered to service design facilitators (NN:6).

The findings presented in this article suggest that it is necessary to know and consider all the factors that can influence the emotions in a co-creation workshop. In addition, those factors go beyond the workshop; for example, everyday personal and professional situations, interactions between people and between people and their environment. This article proposes a vision of a *co-creation community* in which it is essential to increase the knowledge of emotions and their connection and interaction within the community in order to enhance the awareness of how all participants build the experience of a workshop (Soto, 2021) and the need and desire to increase connectedness with all life forms (Kahn, 1997; Keller & Wilson, 1993).

2. Conceptual Background

The concept of emotions goes far beyond a single definition developed by specific disciplines. Nonetheless, these perspectives can contribute in constructing a definition and common understanding and in this case can serve as a bountiful meaning for design. The psychologist Fridja (1986) describes emotions as phenomena in which behaviour, physiological response and subjective experience have an encounter. In psychology, there are different definitions related to the intensity of emotions and their combinations. This paper follows the perspective of evolutionary psychology, which distinguishes between basic or primary and complementary emotions (Desmet, 2002). Different authors use different definitions of basic emotions (Bloch, 2008; Ekman, 1971; Frijda, 1986, 1988; Izard, 2009). This study utilises Bloch's (2008) six basic emotions—joy, anger, tender love, erotic love, sadness and fear—and all the possible combinations between them. These are claimed to be universal (the same for any culture), and they manifest with moderate intensity. *Complementary emotions* are combinations of the six basic emotions. They combine two or more basic emotions with different intensities, and the outcome depends on those combinations.

In the field of design, the works of designer Pieter Desmet and engineer Donald Norman are relevant references. Desmet's (2002) approach focuses on how designers can develop new ways to create emotional connections between products and their users. Meanwhile, Norman's (2004) work is connected to the human response and its relationship with technology. Both are related to the emotions humans experience when they interact with products as well as the emotions that can be triggered in the interaction with other people about a product. According to Desmet (2002), emotions can arise from a direct or indirect relationship with a product. By connecting his work with the co-creation approach, the way in which interactions affect and influence emotions becomes much clearer.

Moreover, this paper finds inspiration in the *community-centred design* approach (Cantù, Corubolo & Simeone, 2012) as a way to conceptualise co-creation environments as creative communities and also to broadly understand a community as something in which not only humans are involved. The holistic understanding of what constitutes a 'community' in this article is connected with the ecosystem approach, whereby a community (or ecosystem) could be described as 'a dynamic complex of plant, animal and micro-organism communities and their non-living environment interacting as a functional unit' (Convention on Biological Diversity, 2006, Article 2. Use of terms section). In this sense, co-creative environments in service design practices can be seen as dynamic ecosystems in which the participating humans interact with and affect each other (and their emotional states) alongside a multitude of other non-human elements, which also influence the overall process, experience and generated outcomes.

The discourse on service design has widely evolved, moving from an original focus on the discipline, such as interactions and interfaces, to investigating the deeper relation between theory and practice to better understand the complexity of the interactions, relations and

experiences involved (Sangiorgi & Prendiville, 2017). Co-creation is a combination of tangible and intangible outputs (Horvath & Carpenter, 2020), where the interaction of the participants allows the merging of their perspectives, opinions and experience, contributing to a participatory practice where emotions arise spontaneously. Given that participatory design is here viewed as a collective creative practice in which facilitators and participants shape the process (Sanders & Stappers, 2008), emotions can be triggered both by the service designers facilitating the process and by the collaborating participants. Accordingly, service designers must be flexible to deal with the constant flux of situations that emerge during co-creative practices (e.g. during workshops or design sprints). This flexibility and adaptation requires specific skills to conduct the design practice since adjusting to the emotions involved can be a challenge. Social, communication and empathy skills are essential for succeeding in co-creative processes (Miettinen, Rontti & Jeminen, 2014).

Co-creation workshops typically involve individuals who have their own personalities, professional and cultural backgrounds, personal goals and expectations and respective lives outside of the workshop setting. Therefore, the facilitators' and participants' emotions can be affected by the many co-existing factors that are present in such collective creation processes. Indeed, emotions are also driven by the personal situations and previous experiences of people, which lead to predispositions in their interactions. The visceral level is the most primitive part of the brain, and it reacts positively or negatively to environment stimuli, such as temperature, lights, colours, smells or shapes (Norman, 2004). The complexity of emotions in an interactive environment is affected by a set of factors related to the present perceptions and judgements of the participants based on their previous experiences. Although present and prior experiences may sound very ambiguous, the purpose of describing it in this way is to indicate that the variables that influence people's emotions are not only an automatic response in the face of particular stimuli. This makes it harder to recognise the emotions related to the service design process and to be open to the emotional state of others during the workshop. By improving their awareness of the participants' emotions during a workshop, service designers could more successfully adapt the flow of the workshop to create the optimal experience for successful participation and collaboration.

3. Research Methods

This paper considers data collected in two case studies. The first (CS 1) was an advanced service design course in Finland. The second case study (CS 2) consisted of three design sprints (workshops) carried out in Gothenburg (Sweden), Tallinn (Estonia) and Rovaniemi (Finland). Part of this material was previously published, focusing on similar themes discussed in this article (see Soto et al., 2020a and Soto et al., 2020b). Finally, this article uses material collected through a short online open-ended questionnaire, seeking to collect views from co-creation facilitators on the external factors that could impact the emotions of both participants and facilitators.

For both cases studies, the use of a specific matrix is essential to understand some critical aspects related to emotional perception. The focus of the matrix "Emotional Map" developed for CS 1 was on the emotions of students when they play a role as facilitators of a workshop. The focus of the matrix "Emotional Record" developed in CS 2 was specifically on the participants' emotions. In both cases, service design in healthcare was the main topic of the workshop. The purpose of the research strategy in CS 1 and CS 2 was to better understand the dynamics in a single setting (Eisenhardt, 1989) and to identify multiple levels of the information and proceed with the analysis (Yin, 1984). The additional questionnaire was aimed at asking facilitators their opinions about the other factors based on their experience to further develop the claims brought forward by the authors in this article. The tools used for CS 1 and CS 2 were as follows:

Emotional map: A visualisation of emotions according to their pleasurable or unpleasant characteristics (Van Gorp & Adams, 2012) (see Figure 1).

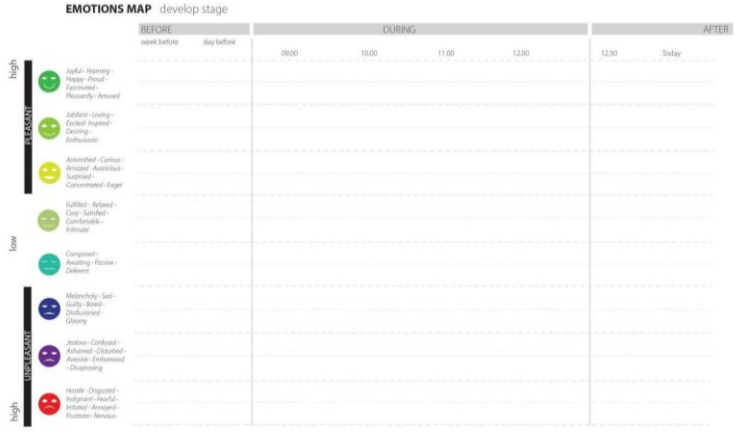

Figure 1. Emotional Map tool

Emotional record: A brief survey to identify the emotions experienced every day during the workshop (see Figure 2). The nine emotions displayed in the survey are a combination of the six basic emotions (Bloch, 2008) and the most common emotions identified in the “Emotional map” tool.

Figure 2. Emojis used for the emotional record matrix

4. Findings

This section shows the results from the data analysis and the corresponding reflections. The findings are organised in two sections: (1) *Variation of emotional perception,* where the data illustrate the fluctuation of perceived emotions according to the stage of the workshop; and (2) *Invisible factors that influence emotions,* where the respondents identified factors regarding their own practical experience and opinions that can influence emotions. Both sections merge results from CS 1 and CS 2 and the online questionnaire.

4.1 Variation of emotional perception

The emotions experienced as a facilitator are diverse and depend primarily on the practical experience that one possesses. Personal skills are an essential role in the facilitator's performance, yet they are not part of traditional service design training: 'The facilitator's personality is essential in her or his role, but none has received specific training to handle emotions' (comment from a facilitator, CS 1). In both case studies, some differences can be observed, mainly depending on the experience of the facilitator.

The facilitators' emotions during the workshop are intense and fluctuate depending on their practical experience; for example, the workshops they conducted previously gave them the knowledge to handle different types of situations with flexibility and wider understanding this define their emotional perception, more or less pleasure, during the process. However, in CS 1, even for those who felt unpleasant emotions during the workshop after a few days, they remembered just the good emotions related to *satisfaction* and having achieved something. Meanwhile, CS 2 showed less fluctuation of emotions. In general, *joy, satisfaction* and *astonishment* were the most common emotions.

The Emotional Map tool used in CS 1 shows the perception changes during the workshop and around one week after the workshop (see Figure 3), when students reconstructed the emotions experienced according to their memories. The visualisation of this representation shows the fluctuation of emotions before and during the workshop, moving from pleasant to unpleasant emotions, although the display of emotions after the workshop shows less variation, with more neutral and pleasant emotions.

Figure 3. Emotional map responses by the three groups

Before the workshop, the emotions of the students who would act as facilitators were diverse, and many of them were related with the expectations and challenges of being the

host or leader of the activity. Therefore, the respondents added some extra emotions or emotional comments to the matrix list, such as: *we know what to do, enthusiastic & nervous, awaiting*, *concentrate*, *indifferent*, *sad*, *guilty*, *confused*, *fearful*, *excited*, *worried* and *nervous.* According to their answers and comments shown in the matrix, the emotions identified before the workshop extended until just before the workshop began. After the first intense part, the emotions were more related with a 'relief state', when all was running as expected, while the emotions in the last part were divided into boredom and happiness. As an example of the emotions before the workshop, one of the answers from the online questionnaire explained the combination of pleasant and unpleasant emotions: 'I love to meet and interact with people, but there are several technical (not only technological) issues that I need to be sure of'.

Comparing both case studies and the online questionnaire shows that the facilitators' emotions were quite similar independent of the type of workshop. Although this might seem obvious, when consulting the facilitators about the emotions they experienced, they stated that it was an aspect that they had not previously reflected upon.

4.2 Invisible factors that influence emotions

The process of recognising the emotions experienced during the co-creation practice is complicated because people in general do not have accurate knowledge to define a precise emotion in a specific situation. Here, most of the answers focused on facilitators' experiences during a workshop, assuming that the emotions were triggered by the ongoing interactions. One of the most challenging aspects was determining which factors influenced the identified emotions, and even the process of distinguishing those emotions might have been affected by factors external to the specific interactions that occurred during the workshop. According to the facilitators of CS 2, they considered all the structural aspects of the space (e.g. light, walls to place papers, place linked with the project) to be important, making some connections between emotions and the environment, but just as a functional part of the activity.

People's emotions are a complex set of elements. Emotions are the reflection of the history of their interactions with different communities (e.g. family, friends, work, gym), the various situations they have faced and the way they have solved or reacted to each of them and their experiences and the growth they have enabled. People are influenced by their surroundings and the communities in which they interact; this can be seen in their lifestyle decisions and behaviours (Tolosa, 2013).

In the online questionnaire, the respondents were asked about their opinions about other or external factors that influence emotions in co-creative environments. The purpose of the questionnaire was to explore factors beyond the planning, structure or any other activity that they commonly regarded as essential to running a workshop. According to their answers, *prior* to a workshop, the external factors could be elements such as the tensions inside the organisation (between participants if they know each other), the stress related to

the thought of meeting new people, the level of clarity regarding the purpose of the workshop or the language being used in the international workshops. The answers regarding the factors *during* the workshop were more extensive and detailed and thus likely easier for the respondents to identify. These answers have been organised into four topics: the atmosphere, the facilitator's skills, the workshop structure and the participant's life outside the workshop.

Table 1. *The factors related to the definition of the emotions in a workshop environment*

Topics	Examples
The atmosphere *All the characteristics of the room and workshop dynamics.*	Lights, temperature, smell, the environmental conditions, the infrastructure and the participants' freedom to express their emotions.
The facilitator's skills *The experience and proper attitude to guide the workshop and handle possible situations.*	'The way the group is being approached by the facilitators and how he/she/they are focusing to that workshops activities' (a questionnaire respondent) and 'how well it's facilitated' (a questionnaire respondent)
The workshop structure *The workshop design and the decisions behind it.*	All the decisions about the methods used, timing, dynamics, tools, materials, the topic or the purpose of the workshop. Nowadays, the workshop characteristics, such as face to face, online or hybrid.
The participant's life outside the workshop *Every person's history and reality shape his or her personality and daily attitude.*	'The group of people that is present in the workshop, e.g. if someone is having a bad day, that affects others as well' (a questionnaire respondent); 'For example, if one participant gets a message from dentist during the workshops that her appointment for afternoon is unfortunately cancelled. This person had a fear of dentist and now immediately feels more relaxed' (a questionnaire respondent).

There were some clear needs and a desire to affiliate with life or lifelike processes. This is reflected in human–nature interaction, which defines the cognitive and emotional characteristics of humanity. There is also an intentional human–nature emotional bond, and as a consequence of this bonding, the protection of nature is a natural reaction to this connectedness (Lumber, Richardson & Sheffield, 2017). The interactions in a workshop seek to achieve such connection, and although there is always a highly personal component, the facilitator can contribute to guiding that feeling of belonging. The facilitator is a guide in this process, as described by one of the questionnaire respondents:

> I have noticed that it is important to the participants to know that even if they are working independently, the facilitator is there to help if there are questions or problems, it is important to be present during workshops.

The case studies provided an overview of the emotional experience in a co-creation workshop, the knowledge of case studies respondents about emotions and the lack of precision in its identification. The answers to the online questionnaire added more detail about the factors that influenced the facilitators' emotional perception. The three methods used provide a visualisation of the emotional perceptions of the facilitators and participants. Although the identified factors could be examined in more depth in future research, this article shows that there are also many unexplored areas related to the emotional flow of collective creation and what defines it.

5. Conclusions

The data collected from CS 1 and CS 2 and the questionnaire give specific information about emotions but also raise new questions. The results and reflections in this article suggest that understanding emotions within a community requires consideration not only of the visible part of the interactions but also what happens with each person. There are numerous factors that affect the attitudes, decisions and behaviours of the participants, that is, the 'world' behind each participant, and life does not stop while people are in a workshop. All of these factors, with more or less intensity, contribute to building a specific atmosphere for the co-creation experience.

The article highlights that emotions are part of a complex group of factors, which depend on the participants themselves, other situations related to them and the conditions around them. The way in which participants process all these experiences depends on the individual and the specific situation. Therefore, emotions are not only a direct consequence of a person's momentary experience; rather, they are a sum of elements, including the recent transportation experience, smells, music, colours, temperature, family issues, health problems or work-related situations. In this sense, facilitators must develop the ability to forecast situations and nurture collective creation environments, considering all the factors that influence the participant's experience.

The real challenge is to generate an emotional climate that supports a stimulating co-creative environment. It is crucial to consider all of the participants in the space, not only people (e.g. users and stakeholders) but also the specific conditions of the space and the environment (e.g. non-human living beings, climate, culture). The opportunity for the facilitator is to increase his or her awareness of everything that constitutes the situation, fostering empathy as a natural response when interacting with others and making the participants feel like part of the definition of the workshop's atmosphere.

About the Authors:

Mariluz Soto is a researcher in the service design research group Co-Stars and a doctoral candidate at the University of Lapland. Her research interests are the relation of emotions with design, community interactions in co-creation practices, communication and nature.

Caoimhe Isha Beaulé is a doctoral researcher at the University of Lapland and a member of service design research group (Co-Stars). Her current research focuses on the social and cultural dimensions of participatory design in the perspectives of design for sustainability.

Satu Miettinen is a professor of service design at the University of Lapland. She works as a Dean of the Faculty of Art and Design. She has a strong design research interest for the complex, extreme and marginal contexts. Her research interests include the areas of social and public service development, citizen engagement and digital service development.

Abstract | This paper describes the planning and implementation of the *Food Futures Teaching Cluster*, a collaborative project that brings together faculty and students from the design arts and humanities to explore and engage with current conversations promoting local and sustainable food practices. This teaching cluster involves two concurrently taught courses taught by two of the authors: American Food Cultures (a comparative studies seminar) and Photo-Graphic Design (Introduction to Visual Communication Design). With the assistance of the third author (Department of English), who participated in curriculum design and met with students as a consultant with expertise in visual rhetoric, students in both classes collaborated to address the topic of food futures in discussion, research, writing, and design. This teaching cluster structure draws upon evidence-based teaching practices commonly acknowledged in teaching and learning research. It presents students with an opportunity to engage in collaborative, experiential learning with a long-term project that results in real-world impact for actual audiences. Over the term, the authors observed, documented, and analyzed how students developed a range of written and visual compositions presenting stories, facts, viewpoints, and emotions related to the *Food Futures* theme. This paper highlights students' reflections on the topic of food sustainability practices and the iterative, collaborative teaching process. Students additionally tie these thoughts to greater insights about their impact as human beings on nature. This study concludes with a faculty reflection and plans for future work, arguing for this approach's capacity to improve relationships among ourselves, our environment, and our technologies.

KEYWORDS | FOOD CULTURE, SUSTAINABILITY, COMPARATIVE STUDIES, VISUAL COMMUNICATION DESIGN, TEACHING, COLLABORATION

1. Introduction

Collaborative models of instruction in design education have become increasingly commonplace. Whether that takes the form of an apprenticeship model (e.g., having students work with professionals in the field), a mentoring model (e.g., having freshmen work with juniors or senior students), or—in this case—an interdisciplinary parallel course model, introducing design students to different ways of thinking, different approaches to problem solving or critique, can be an effective way to foster creative thought and output from our students. In fact, interdisciplinary design has been a professional paradigm for decades. As Tony Golsby-Smith argues, "Epistemic modes …are being broken apart today as we address the large tasks of our time–sustainability, globalization, diversity, … Interdisciplinary approaches are needed for the practical application of disciplined understandings to the existing world" (Golsby-Smith, 2013). Bringing this model into the classroom presents students with a valuable opportunity to experience this professional collaborative mindset in an educational context.

This paper describes the planning and implementation of the *Food Futures Teaching Cluster*, a collaborative project that brings together faculty and students from the design arts and humanities to explore and engage with current conversations promoting local and sustainable food practices. This collaboration is part of a larger multidisciplinary program at the authors' shared institution called *Livable Futures*, a project created to explore effective ways of combining artistic, scientific, and humanistic methodologies in order to address near-horizon challenges that affect both planetary and human conditions. Individual projects within this collaborative consist of media-enhanced dance performances, artists' talks, software design, and innovative teaching collaborations. In that spirit, the authors bring visual communication design and humanistic inquiry together in a teaching cluster focusing on a topic that involves wide-ranging elements of genetics, environmental science, geopolitics, economics, ethics, and art: in short, the future of food.

Over the semester, the authors observed, documented, and analyzed how students developed a range of written and visual compositions presenting stories, facts, statements, viewpoints, and emotions related to the *Food Futures* theme. This paper highlights students' own reflections on the topic of food sustainability practices, as well as their experience of the iterative, collaborative teaching process. Students additionally tie these thoughts to greater insights about their impact as human beings on nature.

The theoretical rationale for the *Food Futures Teaching Cluster* draws upon a body of research—situated both within design education as well as the scholarship of teaching and learning—that offers a pedagogical framework for structuring the assignments and interactions that the students experienced during the term. Privileging both robust collaboration and wide interdisciplinarity that reaches beyond traditional classroom spaces, the true value of this teaching cluster structure lies in its attempt to ground student work in real world issues meant for authentic audiences, in order to design purposeful, meaningful interventions.

2. Context

Food Futures is situated at The Ohio State University (OSU), a large public research university situated in the mid-western United States. Specifically, *Food Future*s is a project sponsored by *Livable Futures*, "a grassroots network of artists, scholars and activists seeking to share resources and foster creative solutions to survival under planetary conditions of unpredictability and crisis" (*Livable Futures*, n.d.). *Livable Futures* is one of several similar large projects that, together, are known as Discovery Themes. The Discovery Themes Initiative, begun by OSU in 2012, is a ten-year, multi-million-dollar project designed to address global issues or problems, such as Infectious Diseases, Chronic Brain Injury, or Sustainable and Resilient Economy, among others (The Ohio State University, 2012). *Livable Futures* is funded under the "Humanities and the Arts" Discovery Theme, established to increase student engagement, faculty collaboration, and national recognition in the humanities and the arts (Noyes et al., 2016).

Directed by Norah Zuniga Shaw (Professor, ACCAD/Dance), the *Livable Futures* collaborative consists of faculty members and students from various departments, centers, and units within the Arts and Humanities. The physical "hub" of the collaborative is the Advanced Computing Center for the Arts and Design (ACCAD), an interdisciplinary center made up of designers and engineers, animators, artists, and others working within a collaborative research facility featuring open, reconfigurable classroom, studio, and performance spaces. The group includes people from Design, Theater, Computer Science and Engineering, and English, among others. Additionally, the project involves internationally recognized visiting artists, designers, activists and scholars. Among the activities sponsored or supported by the collaborative are media-enhanced dance performances, artists' talks, scholarly lectures, software design, community gardening, a remote "field school" located in coastal Louisiana, and several interdisciplinary teaching collaborations.[i]

In addition to the shared mission and support structure of *Livable Futures* collaborative, other notable university-wide activities were conveniently unfolding during the course of the *Food Futures* that helped establish the exigency of the theme. For one, OSU officially launched its Sustainability Institute during the spring of 2019, a multidisciplinary center created to promote research, teaching, and community partnerships aimed at supporting sustainable practices (Sustainability Institute, n.d.). Among the projects undertaken by the institute—and a main source of context for the teaching cluster—is The OSU Panel on Food Sustainability. To help address issues ranging from food insecurity, dietary health, economic stability, and environmental impact, this panel established a goal to "increase production and purchase of local and sustainably sourced food to 40 percent by 2025" (The Ohio State University Panel..., 2018). As the authors continued planning before the term, we identified opportunities to engage students in the larger conversations surrounding food on campus and in the community, such as relevant events to attend, guest speakers, and venues to present student work, detailed in the following section.

The central goal of this initial planning stage was to build a collaborative framework incorporating elements that would successfully enhance the students' learning outcomes. Many of the ideas we implemented have been explored in the context of other courses, but we anticipated that they might transition effectively into our teaching cluster. More generally, researchers in the scholarship of teaching and learning have long published on the advantages of interdisciplinary collaborative teaching (Ebert, 1999; Shibley, 2010; Bryant, et al. 2014). Those advantages include widening your sphere of pedagogical and subject-matter expertise, exposing students to a wider audience, and modeling the kind of collaborative learning/working community often seen in professional settings, among others. In the world of design education specifically, there is a growing body of literature that speaks to the need to develop effective, replicable frameworks for collaboration (Poggenpohl, 2009; Davis, 2013; Lane and Tegtmeyer, 2020). Despite the institutional norms that often hinder cross-disciplinary collaborations (e.g., difficulty scheduling, departmental budgets, differences in tenure requirements), advocates that believe in the benefit of the approach advise faculty to recognize the challenges to anticipate ways of working around them (Davis, 2013). Sharon Helman Poggenpohl (2009) argues for the need to develop stronger theories and models of collaborative education in design based on the "recognition that innovation is often the result of collaborative work" (137). Lane and Tegtmeyer's *Collaboration in Design Education* (2020) identifies the various types of collaborative relationships in design education contexts, from working with peers and design faculty, to interacting with students and faculty outside of design, working in conjunction with partners from industry and academia, and even members of the community at large. In order to foster stronger critical thinking and creative production, *Food Futures* sought from the outset to implement this wide range of collaborative relationships throughout the term, which we describe in greater detail below.

3. Course Descriptions, Outcomes, and Collaborative Structure

Contemplating the issues associated with how we cultivate, process, and distribute food is an integral part of envisioning what shape our livable futures might take. This teaching cluster involves two specific courses, taught during the same term at approximately the same time by two of the authors: Photo-Graphic Design and American Food Cultures. With the assistance of the third author (Department of English), who participated in curriculum design and met with students as a consultant with expertise in visual rhetoric, students in both classes collaborated to address the topic of food futures in discussion, research, writing, and design.

Central to the planning process from the outset was the guiding question: could we create a productive teaching collaboration, one that brings these two separate classes into conversation with one another in order to explore a deeply relevant topic from two very different disciplinary vantage points? This teaching cluster structure draws upon evidence-based teaching practices commonly acknowledged in teaching and learning research. It

presents students with an opportunity to engage in collaborative, experiential learning with a long-term project that results in real-world impact for actual audiences.

Working in small teams, students developed a variety of design projects (e.g., design journals, food landscape photo-essays, posters, visual narrative book, etc.) as part of a larger campaign to help raise awareness of sustainable food practices in general. More specifically, these projects align with a goal established by the university's Panel on Food Sustainability, which is to have the university purchase 40% of its food from local and/or sustainable sources by the year 2025. These project deliverables were displayed and distributed to reach students, staff, faculty, and other relevant audiences within the greater community.

3.1 Course 1 – Introduction to Visual Communication Design, Photo-Graphic

Photo-Graphic Design is a studio course where students explore form in photographic, typographic, and graphic elements to create various levels of integration and juxtaposition. Sophomores from visual communication design major are taken through a step-by-step process that encourages exploration using traditional and digital applications for creating type and photographic compositions. Students apply design principles and visual strategies of word and image to convey connotative and denotative meanings. Throughout the 15-week semester, the course consists of design lectures, topical research, reading discussions, presentations, and critiques. In this particular section, students developed a series of three design projects (e.g., design journals, graphic posters, and visual narrative accordion book) as part of a larger campaign to help raise awareness of sustainable food practices in general.

Figure 1. Food Diary, a type and image composition sketchbook, including images of sample student sketchbooks as well as students presenting work to one another.

The first project required the students to document their encounters of food from different occasions within a week that would require them to draw upon all sorts of emotions, intellectual ideas, and aesthetic expressions. Inspired by these sources, each student created a design diary in a sketchbook format to visually and verbally present his or her own stories, statements, facts, viewpoints, and emotions related to the food topic (Fig. 1). To compose their type and image elements the students applied various design considerations involving complex visual relationships of scale and space concerning form and counter-form relationships and the overall visual syntax and semantics representation of letters, words,

sentences, and paragraphs. Students were encouraged to use graphic support elements to provide additional structures and visual guides.

The second project built upon the food diary that was created in the previous exercise. Each student was guided to develop a distinctive story based on the food experiences presented in the sketchbook. The students continued their type and image composition explorations with a focus on expressing and conveying the meaning and message of their selected food story in a poster design application format. Students formed smaller teams to help each other to identify unique visual themes for their poster concepts. They discussed and applied various communication and persuasion principles of rhetoric based on their required reading materials: v*isual simile*, m*etaphor, personification, metonymy, synecdoche, visual and verbal pun, hyperbole, antithesis, irony,* and *allegory* (Meggs, 1992) to strategically assemble the different forms of photo-graphic elements and create a larger visual impact. Each student produced two food story posters and applied a different design composition for each one that was based on one of four approaches to type and images interaction: *Separation* (when the type and image operate independently), *Fusion* (when the type and image blend to form a unity), *Fragmentation* (when the type and image disturb or disrupt each other), and *Inversion* (when the type and image trade place) (Skolos & Wedell, 2006).

Moving away from letterforms, the students continued to explore the dynamics of form and counter-form within photographs, as well as the interaction between type and image for their final project. This exercise involved designing a progression of pages in book form, using an accordion fold structure (Fig. 2). The range of compositions throughout the book required the students to incorporate type and photographic images that flow in a rhythmic theme. Their studies should consider form progression, juxtaposition of image and type, and visual connection and comparison. The visual and narrative progression must grow from the texture of a body of type to the inner forms of photographs. The aim for this exercise is to reveal photographic forms, not simply to display pictures (Grear, 2006). The visual rhythmic sequence is open for interpretation. The turning of each page and spread should offer surprises while still create a consistent mood throughout the book.

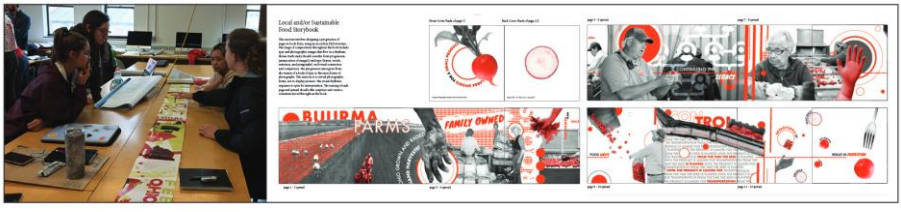

Figure 2. Form & rhythmic progression accordion book overview, including image of students sharing their projects, as well as a sample completed student book.

Each student began this exercise by using the visual and written narrative developed from the previous food diary sketchbook and poster projects. Their design composition

explorations progressed by adding new images, text, and support graphic elements to expand on the photo-graphic form and narrative sequence. At this stage of their practice, the students were more mindful of design considerations regarding graphic space, image cropping and sizing, type and image relationship, tone and texture, motion and implied motion, repetition and rhythm, field of tension, and visual unity (Cullen, 2006; Meggs, 1992).

3.2 Course 2 - American Food Cultures (Comparative Studies Seminar)

American Food Cultures is a course that explores the various ways that culture has shaped our nation's attitudes and practices surrounding food production and consumption. Drawing upon the emerging field of food studies, this course takes a historical perspective on the development of the food system in America, as well as the discourses and visual cultures associated with "American" food. Throughout the term, students contend with topics such as how the distinctive iconographies of Southern hospitality and "ethnic" cuisines have coopted and distorted experiences of colonialism, slavery, and immigration. Students also explore more recent cultural movements such as the rise of "rational" and "scientific" constructions of dietary requirements. Connecting these discourses to contemporary concerns about industrial food and the American diet, a central goal of this course is to raise questions about the cultural politics of efforts to transform the food system in pursuit of more sustainable and equitable ends.

Students in this course read from a number of texts that included Abigail Carroll's *Three Squares: The Invention of the American Meal*, Michael Pollan's, *The Omnivore's Dilemma*, and Carlo Petrini's *Slow Food Nation*, among others. In addition to regular readings and discussions, students also wrote several analytical papers and—most relevant to the teaching cluster—completed an assignment called "Mapping Our Foodscape." This assignment had students create a visual display, as either a poster or by using the online presentation tool Prezi, of their depictions of the foodscape as they experience it (i.e, the physical locations, cultural spaces, institutional settings, and discourses that shape our food environments). These displays were required to include:

- Representations of the spaces and places where students regularly "gather meaning" from food
- 4-5 images (photos, sketches, clipart) illustrating key meanings in/of those places
- 3-4 quotations (or concept/terms) from the readings explaining important distinctions

Ideally, "Mapping Our Foodscape" is an assignment designed to encourage students to interrogate how their university campus organizes or influences their relationship with food.

3.3 Collaborative Structure

The faculty team met prior to the term to create the kind of learning experience that, ideally, would create valuable collaborative moments bridging the two courses in order to promote knowledge exchange as well as a sense of community and a "real life" audience. In creating

this anticipated collaborative structure, we consciously drew upon evidence-based teaching practices commonly acknowledged in teaching and learning research (Harvard Initiative, 2020). Such practices included: creating experiential or authentic learning objectives, offering students sustained or "process-through" feedback on major assignments, and providing peer-to-peer learning opportunities. For example, at several points during the first main assignment for each class (the food diary sketchbook and the foodscape project), both classes interacted in several ways, including attending the same lectures, helping one another brainstorm, sharing drafts of projects and soliciting feedback, and showcasing their finished products. Ultimately, our goal was to present students with an opportunity to engage in a collaborative learning experience centered around a long-term project that results in real-world impact for actual audiences (Fig. 3).

Figure 3. Collage depicting several collaborative moments throughout the term.

We also realized that as the term unfolded, a big component of our approach was emergent and improvisational, as conditions on the ground led to us to revise our plans along the way. To an extent, we anticipated that we would invite potential guest speakers with specific expertise in our topic. The more we planned, the more we saw opportunities to connect the work of these classes to the events and organizations within the broader university community. For one, there was the previously mentioned Panel on Food Sustainability, which suggested for us an opportunity to promote and raise awareness about that initiative. In a related vein, OSU would soon be launching its new Sustainability Institute later that term. We also identified local groups such as Best Food Forward and Slow Food Columbus that could help deepen our understanding of the broader context of food advocacy and activism. Also, the dancer/choreographer/performance artist Ann Carlson was scheduled to perform her orchestral movement piece, *The Symphonic Body/Food,* later in the term. This event in particular allowed the design students a real-life venue for displaying their posters (and also an opportunity for one of the authors, Rick Livingston, to actually take part in the

performance. In part a result of the posters being well received, there was a follow-up request by coordinators from the Methodist Theological School in Ohio to have the posters on display during their conference “On Food and Faith: Ministry in the Time of Climate Change.” Conference attendees included religious leaders, scholars, scientists, farmers, activists, and (perhaps most notably) former Vice President Al Gore (Fig. 4).

Figure 4. Food poster overview, including poster presentations at The Symphonic Body/Food performance event as well as "On Food and Faith” conference.

4. Student Reflections

To better understand the impact of the teaching cluster experience on students, the instructors drew upon a variety of reflective instruments for analysis. This included student feedback produced and collected during the semester—design statements, discursive evaluations, and end-of-term feedback—in addition to reflective questionnaires sent out to a subset of students from the design course. While detailing the entirety of this feedback is beyond the scope of this short paper, we can say that, generally, students found the collaborative structure and thematic focus to be valuable enhancements to the course. We eventually intend to collect additional student data and feedback to produce a more detailed analysis of these findings in a future project. Below, however, we highlight design student responses gathered after the term had ended, which were based on prompts asking about changing mindsets and behaviors, attitudes about the collaborative structure, and its effect on the design process.

1) How did your thinking about food change over the course of this semester?

- AMBER: Through the course of the semester, my idea of food expanded greatly. Through this project I realized that food was a topic that covered more than the

act of simply eating it. Before the project I had strong views on animal rights dealing with food, which I highlighted in my work. Yet through my research and through seeing the research of my peers, as well as all of the lectures and lessons we learned in the course, I learned that food deals with sustainability, culture, racial injustice, obesity and starvation, economics, way of life, mental health, and so much more. After the project, I became more aware of how food affects my own life, and what I can do to make a better impact through food.

- CHRISTINE: Starting the semester off I was kinda of skeptical about completing an entire design course just about food. But as the semester went on, I realized there was more to food than just eating. […] Over the course of this semester, I was able to grow as a designer as well as an individual. I had the opportunity to learn about the importance of local and sustainable food. Food that is produced locally and sustainably is not only healthier but has less harmful effects on our environment.

2) Reflect on the collaboration—how would you describe the experience of working in tandem with the other class?

- AMBER: Working in collaboration with the other class causes me to see how designing for a mission such as food could be done with other non-creatives. The things I learned from the other course's class members and professor touched more on the idea of how food affects people as a whole. The other course gave me insight that I didn't consider, and caused me to dive deeper into my research. It also caused me to be conscious about the way my poster/design items were worded, as that too could make all the difference.
- ETHAN: Collaborating with other students was exciting. I often find that my design work improves when I get feedback from other designers and non-designers alike. I also think that there are opportunities to make this collaboration more successful in future years. There were instances where both classes could have benefitted from more instruction and guidance, because sometimes we did not know what we should be talking about with each other. As a design student, I was able to develop my work based off of what the other students said when they looked at my work, but I did not know how to give them feedback on their work because it was more difficult for them to explain or show the kind of work they did, given the medium and nature of their work.

3) Have you engaged in any additional actions based on exploring this topic of local and sustainable food? For example, have you changed your eating habits, joined or volunteered for a food-based organization, or engaged in similar activities?

- LILY: I have changed my diet since this semester, and I have cut dairy and meat out of my diet for the most part. Though I've not yet stuck to a strict type of diet (vegan, vegetarian, etc.), I've become a lot more conscious of what I feed myself, as well as how the dairy and meat industries are incredibly harmful to the

environment. Though switching over completely to purchasing dairy and meat alternatives is pricier, I want to continue to explore food options and support food production that is healthier for the environment.

- AMBER: From the course and my personal research I became more aware of animal rights in the food industry, and now choose to buy pasture-raised eggs despite the fact that they are $4.59 a carton, because I am essentially paying for the animal to know happiness. […] After the course, I realized that one day I want to own my own chicken coop so that I don't have to be a part of the cruelty that is going on, and plan to have my own chickens after college.
- SARAH: I have become much more aware of what I eat and where it comes from. Because I physically saw where lots of produce in Ohio is grown and collected, I sometimes find myself reflecting on that experience and my accordion book project when shopping for produce at my local Kroger/Giant Eagle. I also find myself going to restaurants that I know have locally sourced food.

4) How has this experience changed your understanding of concepts like "natural," "biological," or "human"?

- ETHAN: I've learned that words like "natural," "organic," and "healthy" can be extremely misleading and require a lot more inquiry when making shopping decisions. […] I think that this project opened my eyes to how multi-dimensional food is and how much emotion is behind it. There are as many experiences with food as there are people in this world. In the research I conducted on the dairy industry for my design project, I found such complexity behind every aspect of the process. I had approached the project initially with a strong stance about the treatment of dairy cows, but through my research, I learned to treat this issue with nuance.
- AMBER: After the course I became more aware of the idea that companies like to hide behind vague words like natural, fresh, and organic. The course made me realize that the only way to know for sure what is going on behind the scenes is to do my own research. The course caused me to realize that the idea of "natural" is what we define it as. […] The greatest thing that the course did for me was that it caused me to be more aware of food, from the act of cooking it, to all of the elements it touches. Essentially, I realized that to eat is "human." We all need it, and that need can be greater than we know, therefore it is up to us to find a solution to feed the people without harming our planet.

5. Conclusion

Reflecting on this experience and how it aligns with the values of the larger *Livable Futures* collaborative, the three authors approached this teaching cluster as an exercise in stepping outside of our intellectual comfort zones by engaging with individuals from other academic

disciplines, each of us bringing our own training, knowledge, and skills to the conversation. Our goal was to create a visual communication design mindset (as well as ourselves) that embraces values of understanding, empathy, and compassion in design thinking and practice in order to address complex issues that affect both humans and nature. By exploring these new approaches to teaching design, we ultimately seek to create the kind of spaces, connections, and underlying ethics that lead to more responsible relationships with one another, our environment, and our technologies. Particularly during a period of worldwide pandemic, we remain mindful of the advice of Lane and Tegtmeyer to explore these new and ever-shifting collaborative pathways. They write:

> "Design faculty are tasked with teaching in an ever-changing world — with advancements in technology our tools are changing as well as access to an abundance of information. This shifts the expectations of what designers need to know on a continuous basis and challenges educators to stay ahead of the curve. In addition to technological changes, the types of problems that designers should/could solve are shifting and becoming more global. Designers have valuable contributions to make not only in business and commerce, but in healthcare, politics, sustainability, diversity, etc. This requires a new type of collaboration, one that is more than passing down of skills and tools and different than experimental community learning spaces, but a way to communicate and work with others outside of their discipline and unlike themselves." (Lane and Tegtmeyer, 2020)

Food Futures is part of an ongoing collaboration between the authors. This multidisciplinary approach to design education is one that we—in slightly different formulations—have successfully repeated for other sections of the Photo-Graphic Design course. In addition to the thematic focus on sustainable food cultures, a version of the course focusing on the concept of water wellness was conducted the previous year, and a course centered around the idea of tree futures is currently underway at the time of this writing. Additionally, one author (Chan) has successfully utilized a version of this approach as a guest instructor in design schools in China and Germany. Whatever the content, the students largely tend to respond positively and enthusiastically to the general approach, the shared sense of mission and purpose, and the opportunity to situate their design work in a context that has real-world impact. With that in mind, we plan to continue refining this approach, adapting it to timely and relevant contexts along the way.

*Saumya.pande@iiad.edu.in

Abstract | These The paper aims to ascertain the connection between the intensely embroidered expressions of Shershabadi women and their environmental landscape in the Indo-Gangetic plain, tracing the impermanence of their cultural footprint dux e to geopolitical crisis induced migration. The constantly changing topography of the region, the flood rich plains and displacement from their lands impact the formations of individuality and expressions of culture, questioning the notion of identity as a community. We argue that the river is both the cause and causality of Shershabadi expression, deeply rooting the community to their land and shaping their aesthetics. Through anthropological frameworks we analyse the primary and secondary research data, presenting a multiscalar, multistressor assessment of vulnerability at rural community level. Integrating migration mapping with culturally inclusive research, our objective is to establish the unique evolution of this community, their culture and embroidered expressions known as “Kheta”, worthy of getting a geographic indicator status.

KEYWORDS | CULTURAL FOOTPRINT, MIGRATION MAPPING, #KHETAKISHANGANJ, INDO-GANGETIC FLOOD PLAINS, GEOGRAPHICAL INDICATION

1. Introduction

The paper aims to highlight the connection between **land** – Ganga-Brahmaputra delta region, India-Bangladesh – its **people** – Shershabadi community living along the banks of major rivers in this region – and their **expression** of embroidered textiles (Kheta). This delta region, crisscrossed by rivers, has witnessed a unique play of land and water without any permanent line of divide between the two. Hence the intention here is to trace these rivers as the lines of life that have shaped the migrations and expressions of Shershabadi community along these life-lines from present day Bangladesh into the neighboring states of India. A multidimensional social phenomenon; migration is yet to be conclusively understood by scholars, cutting across different disciplines. Through our research following the cultural footprint of Shershabadi community, we have attempted to understand the cause and causalities of migration at a community level triggered by shifting of river courses, the ensuing catastrophe, and their impact on human environment as well as material culture. Persecuted by the Mughals and later by the British East India Company (Hoque, 2015), historically claimed to be the direct descendants of Emperor Sher Shah Suri's soldiers, the Shershabadi or Sher-Shah-abadi – Hindi word for population – community's deep connection can be traced back to the Ganga-Brahmaputra delta region.

Initially settled in the land given by Emperor Sher Shah Suri – who ruled from 1486 to 1545 A.D – in Malda district of Bangladesh, the Shershabadi community has constantly moved westwards along various rivers in search of better life opportunities since 1548 A.D and have settled in the Kishanganj and neighboring districts of Bihar in India (Author, 2018).

The rich delta of Ganges and Brahmaputra, silted by nearly 700 rivers (*refer to Figure 1*), makes the dynamics of water and land unique to this part of Indian subcontinent. The constant flood induced emergence and erosion of riverbanks, the political persecution as well as the social marginalization of Shershabadi community gradually led to their psyche marked by a lot of informality and impermanence of life and living, shaping their aesthetics, and impacting the evolution of their unique craft of quilted textiles called "Kheta". Even though the Shershabadis have endured waves of migration across generations, it has only resulted in evolving and strengthening their community identity; their embroidered textile, Kheta, has been instrumental in keeping this identity distinct.

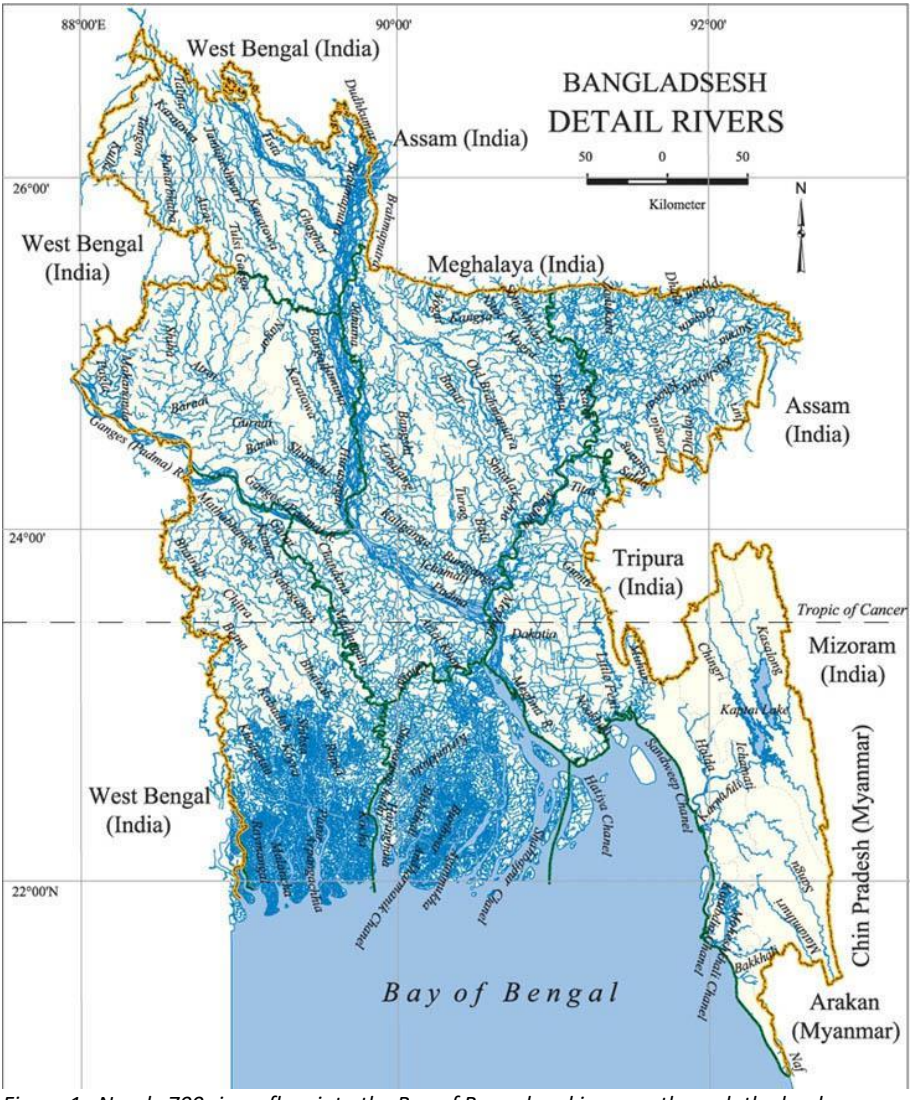

Figure 1. Nearly 700 rivers flow into the Bay of Bengal making way through the land between Bangladesh and Eastern part of India, creating a dense network of waterbodies.

2. Literature Review

In the paper, titled “Sher Shah Abadi community: A study from historical perspectives”, Md. Akramul Haque provides information on the community in general, their Afghan lineage and described them to be the soldiers turned land owners around Malda district in undivided Bengal. He describes in detail the continued persecution of the community first in the hands of the Mughals and later the British rulers of Indian sub-continent. In the recently published dissertation, Mr. Keshar Kumar focus on the informal nature of employment within the Shershabadi community in Kishanganj district of Bihar. His qualitative research for Tata Institute of Social Sciences, focuses on the involvement of Shershabadi women in the informal, hazardous yet skill oriented cottage industry of bidi (indigenous cigarette) rolling. This helps us in substantiating our understanding of impermanence in the daily life of the community and the evolving nature of their expression.

However, in the absence of extensive published literature on the migration, material culture and embroidery expressions of the Shershabadi community, a considerable amount of our secondary research has been dedicated to the writings on movement by anthropologist Tim Ingold and sociologist Richard Sennett. Referencing “Life of Lines” by Tim Ingold and “The Craftsman” by Richard Sennett, we have tried to deepen our understanding of community, their role as a craftsman, the deep rooted connection between life, climate, land, river, walking, imagination and spirit of creation as well as what it means to be “human”. Informed by the writings of Tim Ingold, we based our hypothesis on the fact that the primary tactile contact with our environment is through the feet rather than the skilled hands and hence the material culture and embroidery practice of Shershabadi women is an expression of the migratory path that they have walked on for generations in their vulnerable state. In a series of essays compiled as, “Being Alive: Essays on Movement, Knowledge and Description", Tim Ingold explained the vitality of materials, what it means to make things, the perception and formation of the footprint, the identity of community.

Further, we developed our understanding about the challenges of living along the river banks through the works of conservation architect Marina Tabassum, who attributed the informality and impermanence in the lives of Shershabadi women to the lack of distinct line of divide between water and land in the Ganga-Brahmaputra delta region. We referred to the book, Sui Dhaga published by Wisdom Tree in our research and subsequent claim to get Geographical Indication for the embroidery of “Kheta”. Building our argument on the facts shared by Ms. Niaz Zaman and Ms. Charusmita Gupta in chapter 4 (The representations of feminine in kantha) and chapter 6 (Sujni: the fine needle work of Bihar), we formulated our comparative research methodology and research questions.

3. Objectives of the Paper

The paper has the following objectives:

- To map the migration of Shershabadi community along the rivers in Ganga-Brahmaputra delta.
- To establish the impact of migration on the community, its material culture and expressions, especially on the embroidered textile Kheta.
- To make a compelling argument favoring the grant of geographic indicator status or Kheta.

4. Methodology Followed

Drawing inferences from the extensive primary research conducted in Kishanganj published in our previous paper (Author, 2018) and through ethnographic data driven analysis, we have attempted to understand the relation between the Shershabadi community, their migration over the generations and the evolution of their material culture. The multiscalar, multistressor assessment of vulnerability at rural community level was based on the migration mapping from Bangladesh to the state of Bihar in India. The hypothesis stated in the paper is based on the socio-anthropological approach to understand Shershabadi women artisans at a human level drawing a relation between their skilled hands and their footprints on the river banks in Ganga-Brahmaputra delta. In order to establish the uniqueness of Kheta embroidery, a comparative primary research was conducted through skill mapping and skill development workshops in the villages of Arrabari, Chandpur, Shafaqatnagar, Kharkhari and Kamarmuni. With a sample size of 100 Shershabadi women artisans, three workshops spanning 3 to 7 days were organized in August/ November 2017 and October 2020. A total of 5 new design patterns were discovered in addition to the 8 existing ones (Author, 2018). The authors also conducted first hand interviews with experts Ms. Jasleen Dhamija (veteran Indian textile art historian, craft expert and former UN worker), Ms. Archana Shastri (Textile expert and author), Ms. Sudha Dhingra (Associate Professor, NIFT), Ms. Swati Kalsi (textile designer) and Mr. Shahid Hussain Shamim (CEO, Paribartan, Bangladesh, textile expert and author) to trace the journey of the community and their expression. Through a combination of these ongoing skill development workshops in Kishanganj, interviews with experts in India & Bangladesh and demographic information (Census of India 2011), a set of data was collected in the first stage. The data was analyzed to understand the socio–economic and geo– political evolution of this migrant marginalized community providing vital clues to their unique cultural expression making a case for the Geographical Indicator status.

5. Limitations of Present Research

The connection between the land and the patterns of Kheta was established and elaborated upon by actual samples, documented and researched by the authors across the three workshops held in seven villages of Kishanganj. A total of three academic papers have been authored so far. The first paper, based on the primary research experience in the workshops, details the discovery of the community, their expressions and the design patterns. The second paper tries to establish the uniqueness of the embroidered expressions making a case for Geographical Indication. The present paper (third) traces the origin of the embroidered expressions and correlates the interdependency between the land, people, their migration, and cultural expression through a theoretical framework. Since the last census of India was organized in 2011 and the next one is due in 2021, the data on the present number of Shershabadi women is not conclusive. Today the community is spread across two countries i.e. India and Bangladesh, and it is still a long way to conclusively establish the extent of migration that has already taken place as well as connection with other craft practices that may have impacted its unique evolution to the present form of Kheta (Author, 2018). Hence there is a need for field testing the hypothesis of impermanence across India and Bangladesh, which we have tried to establish in this research paper.

6. To Migrate

Tim Ingold writes, “The things about things, however, is that they *occur* - that is, they carry on along their lines. This is to admit them into the world not as nouns but as verbs, as going ons. This is to bring them to life” (Ingold, et al, 2015, p.16). This quote builds the premise for Kheta to be seen as an *act* of embroidering, filling up complete surfaces with continuous patterns.

> “The river gives and the river takes away; in the face of nature, we are powerless”
> (Shershabadi farmer displaced by flooding of agricultural land)

Kishanganj is home to densely populated villages with smaller cluster of Shershabadi houses called “tolas”. Constructed out of mud, thatched roof and impermanent bamboo structures, these are cramped wall to wall living conditions for families with 10 to 15 members each, providing a sense of security and community identity to these people. The land along the rivers makes the soil extremely fertile due to heavy siltation. The villages here are lined with bamboo forests and vast watery floodplain with intermittent stretches of jute and paddy fields that are lush, green and flat. It takes only little imagination to think of a future scenario, when the Shershabadi population will likely have doubled, and a good chunk of the current agricultural land that they own, will permanently be underwater due to seasonal floods causing the rivers to change courses. Such a scenario could mean that a majority of this community along the river banks would be displaced, forcing them to crowd even closer

together in their villages or else once again migrate from Kishanganj district as geo-political refugees.

Such a catastrophe, even though imaginary now, fits right in with the community's crisis-driven story line. The entire Ganga-Brahmaputra delta across India and Bangladesh, has been witness to multiple woes since the first recorded communal riot around 1671 A.D. due to Mughal emperor Aurangzeb's intolerant religious policies (Lal, 1992). The partition of Indian subcontinent into India, East and West Pakistan in 1946 led to the Noakhali riot in present day Bangladesh in which approx. 5000 people perished and more than 50000 people were uprooted from their land (TIME, 1946); many of these displaced people including Shershabadis, migrated along the crisscrossing network of rivers moving towards India. The 1971 India-Pakistan war leading to creation of Bangladesh as an independent country witnessed further persecution of the Shershabadi community by the retreating army causing mass exodus across international border into Indian states of Bengal, Bihar and Orissa. Poor literacy levels, famine, epidemics, killer cyclones, massive floods, military coups, communal riots, political assassinations, and pitiable rates of poverty and deprivation led this community to survive as migrant refugees in their own lands.

7. To Negotiate, To Survive

As it has been pointed out by conservation architect, Marina Tabassum, "Migrations like these lead to possibility of negotiation, appropriation and optimization." To what extent, has this migration affected the textile expression of Shershabadis is a question worth asking and is one of the primary objectives of this research paper. The clues to the answer remain in the way this community has adapted time and again to the ever changing ways of living along the fertile river banks of Ganga-Brahmaputra delta.

The village lifestyle of the Shershabadi community still continues indigenous practices like building their mud houses, constructing the mud granaries, making of Khatia / Charpoy (cot), hand grinding of spices, making of sun dried pickles, oil pressing, basketry, and catching fish with indigenous tools and techniques. Since the native Surjapuri community are the major land owners, Shershabadi people mostly end up cultivating maze, paddy and jute in the low lying lands that are flooded by rivers during the monsoon causing extensive damage to their standing crops (Author, 2018).

Many of them are *char* dwellers, who inhabit the constantly changing islands (locally known as chars) on the floodplains of region's major rivers—the Ganga, Padma, Jamuna, Meghna and Brahmaputra. These islands, many covering less than a square mile, appear and vanish constantly, rising and falling with the tide, the season, the phase of the moon, the rainfall, and the flow of rivers upstream. Making a life on the *chars*—growing crops, building a home, raising a family—is an extreme example in adaptation that may have evolved them into one of the most resilient communities in India.

The many adaptations across generations can be seen in the way the visual references and practices of making Kheta have evolved. Each pattern in Kheta follows a stitched guideline and is carefully embroidered with precise intuitive calculation, leading to an extremely sophisticated design vocabulary that can be directly traced to the tricks of living on a char. For example, most of the bamboo and mud houses are built in sections that can be dismantled, moved, and reassembled in a matter of a few hours. The houses are built on a raised platform of earth using panels of thatch for the roof. In most of the households, the large granaries built out of mud, serves the purpose of stocking grains as well as quilted textiles (Kheta) that are seen as prized possession in case of flash floods, displaying an immensely practical sustainable and circular way of dealing with their environment.

The real secret of this community's survival is the fact that they seldom ponder over their vulnerable state of living. They have always been under pressure, and since ages their survival depended on their ability to move from place to place keeping the river as the only constant; their line of life. They farm their piece of land (char) for as long as they can, and then the river washes it away. No matter how much they worry, the ending has always been the same. There's no arguing with the soaring river. And yet they make the most of what is available and adapt until the bitter end, and then, when things become impossible, adapt a little more. It's a matter of community psyche — a fierce instinct for survival combined with a willingness to put up against incredible odds — . This can also be seen in the way the Shershabadi women layer their used saris, quilt every inch of it using simple tools like (only) needle and thread giving a new life and purpose to the otherwise worn out fabrics. Their feet that have walked the migratory miles along the river banks, pass on the instincts to their subconscious, drawing on the sense of constant movement across generations; their survival in anonymity erases any individual expression of motifs and their vulnerable selves get captured in the layers that are quilted together providing them warmth against the bitter cold of the landscape.

The designs of footprints are not ready made, nor are they imposed from above upon a hard surface. They are made, as human beings or other animals walk or run along, in a surface that is soft, pliable or absorbent. Thus whereas the stamp connotes immobility and omnipresence, footprints register emplaced movement. For from staking a claim, the indigenous inhabitant leaves footprints in the ground as clues to his whereabouts and expectations, and for others to follow. While a trained eye and touch can read much from a single footprint, even more can be read from a series of prints. Such a series, observed in sequence, comprises a track. If the same track is trodden often enough, the many individual prints merge into a continuous path. One cannot, then, read individual movements from a path, but only those commonly or collectively made. Footprints are individual; paths are social (Ingold, et al, 2015, p.63).

8. To Move, To Connect

> "There can be earth without human beings but can there be humans without earth? And if earth is necessary for human existence, then could we not equally say that human beings are the earth's most general instrument, since they provide the means by which its bounty is recovered? Do people produce upon the earth, or do they assist, like midwives at birth, in harvesting what the earth has produced?...yet the ground still appears as a *substratum* for such activity, an interface between the mental and the material where the sheer physicality of the world comes hard up against the creativity of human behaviour." (Ingold et al., 2015, p.63)

Moving from the approach of looking at textile as "man and his expression" in our earlier research papers, the narrative has changed to appreciating Kheta as an *act* of the land, by the land and for the land. It is not an embroidery anymore but the act of it. It has nothing to do with being an outcome like a textile product, however, everything to do with being the witness to the lives of Shershabadi women.

Figure 2. The intensity and richness of the land gets translated into the lives of Shershabadi community

8.1 To Stay Connected with Land

To appreciate the connection between Kheta and the land it belongs to, let us look at the textile up-close. Traditionally the base material is worn out sari or dhoti that are collected over the years with the intention to breath in new life. For a community of people who own

very little and are constantly moving from the state of permanency to impermanence, the idea of continuity and recycling becomes inherent to their existence. A closer look at the embroidery process reveals an initiation act of removing the edges (selvedge) of the fabric to loosen up the warp and weft so that they can be aligned and moulded to the linear patterns of the embroidery. This act is akin to the process of loosening up the soil before the seeds are sown. Similarly the act of picking the layers by the needle can be compared to the transplanting of paddy saplings which is the main cultivated crop in the region. One can attribute these underlying connections between handling of the textiles to the agricultural wisdom gathered over the ages.

8.2 To Connect with Feet

During the process of quilting in Kheta, once the base fabric is folded into layers over each other, the women squat together to secure the same with stay stitches and practically move over the fabric tracing their footsteps along the stitched guidelines (Author, 2018). The contact of their feet with the textile resonates with anthropologist Tim Ingold's idea of bare feet revealing the ground to be composite and heterogeneous, not so much as isotropic platform for life. The intensity of the primary tactile contact is much higher as the textile is experienced both through the feet and the hands. Assuming that most of the Shershabadi migrations have been through walking along the river banks, does the migration on feet has anything to do with the richness of the textures created by the migrant community?

Figure 3. The intensity and richness of the land gets translated into the intensity and richness of colors and textures in their quilted textile of Kheta

8.3 To Meditate

The act of this embroidery, with equal floats on either sides of the surface making it completely reversible, is a consistent movement of the needle and threads. Groups of Shershabadi women seated on the floor, under the mango tree in their courtyards, participate in this rhythmic act like many monks in meditation. “Far from being merely habitual or ‘done without thinking’ such rhythmic activity calls for intense concentration. This concentration, however, is that of a consciousness that is not confined within the head of the practitioner but reaches out into the environment along with multiple pathways of sensory participation.” (Ingold, et al, 2011, p.18)

8.4 To Weave

> “In both carpentry and textiles, the form of a thing does not stand over it or lie behind it but emerges from mutual shaping within a gathering of forces, both tensile and frictional, established through the engagement of the practitioner with materials that have their own inclination and vitality.” (Ingold, et al, 2015, p.24)

Similarly in the act of Kheta quilting, the way threads are taken from one edge to the other and left as fringes on both the sides, self-finishing the textile, is drawing from the act of basket weaving which is a common practice for constructing houses as well as objects of daily use

8.5 To Remember

> “This surface, for Kant, lies at the very foundation of human experience; it is the stage on which the play of our skills proceeds (and) the ground on which our knowledge is acquired and applied.” (Ingold, et al., 2015, p.37)

The movement of Shershabadi community along the rivers not only took with them the memory of the land but also the contact with the earth, the ground, the surface, the wind and the sky. This is where the community made contact with these elements. On one hand, in those layers of saris is the collective memory of the single footprint, the series of prints, tracks that the prints made and over a period of time, the continuous path that they merged to make. It also has the memory that the thread makes when it comes in with the fabric that has become soft and supple with repeated use. The act of embroidery is the promise to make new memories with renewal of life. The fresh intense colors pulled in to the recycled saris/lungis by the threads are reminders of life being fluid, cyclical and circular, yet not repeating ever.

9. Conclusion – To Revere

> "We should resist the temptation to equate holism with finality or completion. The meeting of minds weaves a whole rope but so long as life goes on, there must always be loose ends." (Ingold, et al., 2015, p.12)

The river is the life line of this land. However, the only permanency in this fluid reality of Shershabadi community is not the land but the presence of the river alongside. The river meanders her way through this land and in some areas is as wide as 12 kms making it revered. The first stay stitch that the Shershabadi woman embroiders in her Kheta, is the walk that she does on one side of the river bank trying to gauge the life on the other side. The thread which is the carrier of her memory in the act of making these quilts, has no beginning or end like the river, allowing a continuity to be embedded within those layers.

About the Authors:

Saumya Pande With 25 years of experience as a designer and educator, Saumya Pande has advocated slow conscious living and conservation of indigenous cultures in her classroom, at global conferences and as a TEDx speaker too. As the founding course leader of Fashion department at IIAD, she is committed to creating an inclusive, rich learning environment with diverse viewpoints, talents and experiences. An alumna of NIFT (Delhi) and NTU (UK), she has the unique experience of setting up design departments of NIFT Chennai, Pearl Academy Noida and IIAD Delhi. Strongly influenced by Indian identity rooted in traditional skills, her creative practice spans across fashion, textile, craft practices, illustration and dance, constantly pushing the limits of body and space. In 2014, her textile installation titled, 'The New Body', was showcased in Florence, Italy. As the co-founder of Zameen Astar Foundation (ZAF) she is creating livelihood for Shershabadi community and conserving their craft of quilted textiles called Kheta. She is currently involved in setting up a unique online museum of brooms in India. A trained dancer, Saumya loves to collect seeds and pods from all over the world.

Indrajit De is a design educator, management consultant and social entrepreneur based in Delhi. His bachelor's degree is in fashion design from the National Institute of Fashion Technology Kolkata. He did his MBA in Strategy and Marketing from Indian School of Business Hyderabad. He is currently consulting to set up a Transportation University for Indian Railways. He is also the co-founder of social collective called Zameen Astar Foundation working towards women empowerment in Kishanganj, Bihar. His research interests include visual storytelling and craft conservation.

The Shape of Drugs: a matter of Human-Centred Design.

Abstract | The importance of drugs in our daily activities is evident. And yet design thinking suffers from relative *inertia* about viewing medications as objects of use and consumption. Conventionally intended as industrial pharmaceutical products obtained based on scientific principles, drugs are both medicinal forms saturated with meaning and technical objects—for the latter, we mean the product's tangible characteristics with which the user has to cope. Therefore, it can be assumed that any medication's efficacy depends on its scientific principles as well as on the sophisticated, hyper-technological or—conversely—prosaic techniques of intake or delivery. An approach to drugs from a human-centred design perspective may thus be aimed at verifying possible correlations between medication shapes and the inefficiency that, as a designed artefact, the medication may produce in terms of identity, understanding, and usability.

KEYWORDS | HUMAN-CENTRED DESIGN, PHARMACEUTICALS, PRODUCT DESIGN, USER BEHAVIOUR, AFFORDANCE

1. Introduction

An object's statutory design is punctuated by different focal points: sometimes these are specific outlooks or points of view; at other times, they are foundational issues that help define the various nuances of that object's essence within the epistemological and phenomenological framework (Molotch, 2005; Bertola & Manzini, 2004).

Technical objects, items, products to be used or consumed, things, tools, apparatus, and gadgets - the focal points around which we centre the facts, experiences and symbolism of objects are all closely linked and yet are also imprecise and fragmentary when used to provide clarity concerning drugs (as solid contingencies), to the extent that their nature as objects, their morphological, typological, experiential and sensorial - even aesthetic - purposes, and their usage, become elusive.

In fact, drugs are part and parcel of our object-driven civilisation, following the same rationale of goods, which is followed by other objects that define the essence of our material culture, including their uses and unhelpful intrusions. As such, they become a constituent part of the physical real-world and the values within which our life experiences unfold.

Specifically, we are referring to experiences that take place as part of self-treatment practices and more specifically to the simultaneously private and political practices and cultures surrounding the body, its wellbeing and health (Foucault, 1985), particularly the forms of daily treatment and drug consumption. When it comes to treatment, there is no maturely developed thought on design for objects or on the subjects' interactions and experiences when they aren't equipped with the necessary training. This can lead to errors, with some having severe consequences.

2. Framing drugs within the system of objects

Considered as objects, drugs and their shapes pose many design challenges:

- As products of the most advanced development stages in the scientific world, drugs pose a challenge for the designer to act as a formal translator that avoids expressing a technical purpose in order to create a shape that generates a better usage experience (Bürdek, 2008; de Seta, 1980; Norman, 2013; van Onck, 1994);
- By incorporating value-based technical-scientific structures, drugs don't solve the problem of "how objects are experienced, what needs other than functional ones they answer, what mental structures are interwoven with—and contradict—their functional structures, or what cultural, intracultural or transcultural system underpins their directly experienced everydayness [...], the processes whereby people relate to them" and what relationships exist between objects and subjects (Baudrillard, 2007, pp. 6-7);

- Cleansed of any symbolism, drugs pose the issues of recognition, understanding, learning through use and making the experience of care accessible;
- Despite emerging as a response to mass production, through medical prescriptions drugs acquire a status of unique exceptionality and their usage becomes exclusive and personal;
- Understood purely as objects that are "tools" for "bestowing" health, the shape of drugs is a design challenge, as we know that even the most marginal, the most banal, or even the most technical object, becomes "aesthetised, culturalised" (Vitta, 2001, p. 312);
- As a precursor to the processes that have dotted the history in which the natural and the artificial - bodies and prosthetic elements - have been hybridised, drugs remain a primitive object, devoid of the design culture that surrounds objects for giving them friendliness and empathy. This is even more applicable, the closer we get to the sphere of bodies and their suffering;
- As objects that feature in everyday life, drugs and treatment procedures lack a discussion about the "strength" of habitual regimes, their *driving habits* (Bourdieu, 2001, p. 178) and the mental habits and their *structuring structures* (Bourdieu, ibid.), which often remain despite changes to the context of use.

2.1 Drug as a daily apparatus

The list of aspects in which a drug-object emerges as deficient can quickly lengthen. This is a sign of its distance from "product design". We would like to dwell on a particular element, whose intrigue lies in the power - beginning with drugs - to broaden design considerations. The problematic broadening, we propose concerns objects - and drugs, when viewed as objects - as an apparatus. In addition to fulfilling a specific function, an apparatus - etymologically speaking - encapsulates the properties of making available and preparing [something], in the sense that it indicates a sequence, but also by "having its own assets" or making something available to someone. It also contains a sense of putting in order, providing a rationale that adheres to criteria. These criteria target a purpose, but also ensure that someone does something, or allows them to do it. Finally, in its "availability", we also find the motivating factor of being inclined or being made to be inclined to do something (Cortellazzo & Zolli, 1999). In an apparatus, the physical tool is therefore accompanied by regulations and a prescriptive "body" (Costa, 2016, p.75) as well as by an exhortative one. Agamben defines apparatus as "something that has […] the ability to capture, orient, determine, intercept, control and safeguard human beings' gestures, conduct, opinions and discourses" (Costa, 2016, ibid.).

Such presuppositions provide a starting point for viewing drugs as apparatus and seeing the treatment system as a whole, combining objects, subjects, relationships between objects and subjects, ordered and pre-ordered actions, prescriptions and provisions that are written,

verbal, formal, codified or constructed in the natural lexicon with which things are made familiar, as imposed or conveyed by an authority (the doctor) or simply self-learned.

As an apparatus, drugs are, in all senses, “social objects”, made up of a concrete “body” (they are material things) and of an invisible corpus consisting of acquired concepts and tacit knowledge, expectations concerning behavior, prescriptions, rules and anything prohibited. They can only “operate” and be effective if the end-user is fully immersed in the cultural dynamics from which those principles are derived (Ferraris, 2005).

Drugs are the meeting point of production interests and a health-related ethic that has been pervaded by economic values. They carry ideologies about recovery and care, and so also about what constitutes an admissible and acceptable therapeutic object. They embody scientific principles, social values, forms of exclusion from or the right to treatment, and conceptions about health policies. As a socio-technical apparatus, they contain forms of hidden power. As a socio-semiotic apparatus, they pave the way for signification processes that follow trajectories back and forth between the society level and individual level, between the level of scientific precision and the level of approximation of daily life, between technical-specialist level and the level of daily incompetence (Landowski & Marrone, 2002).

2.2 Drugs equipment

Drugs are sealed into their pharmaceutical shapes (pill, syrup, suppository, etc.). They are accompanied by concrete and textual objects that are intended to serve as persuaders (aimed at prescribing, laying down sequences of actions, encouraging therapy adherence) and dissuaders (aimed at prohibiting unsuitable or even dangerous actions). This refers to the package insert, the packaging, medical prescriptions, suitable or unsuitable aids to assist with the treatment.

Despite their apparent function as “apparatus”, the language, semantics and practicality of these objects make them unsuitable for this role. Authoritativeness expressed as polished jargon generates refusal; the self-containment of the signs/signals used to order sequences of actions doesn’t possess the required prescriptive strength, the persuasive nature, or sufficient commanding clarity.

Here, we offer an initial exploratory hypothesis that it’s the drugs themselves, in their self-contained formality and functional minimalism, that embody the distinctive element (perhaps because they are dense with ideologies, values, salvific powers) and possess the ability to influence their users’ behavior, at times assuming the role of a miracle object that, being potentially harmful, can instill fear. On account of the values attributed to them, drugs, as objects, seem to embody the same prerogatives as apparatus: moral, ethical and philanthropic discourses, scientific statements, institutionalized medical principles, philosophies of health and social cultures surrounding treatment. The concepts of dependence, addiction and refusal belong to the relations that a subject establishes with the

governing power that certain objects have. However, the abundance of meanings associated with drugs doesn't come with a rich circle of practical-functional instructive signs.

The packaging that contains them and the wealth of information intended to instruct aren't sufficiently strong to orient the experience of using a drug and make it accessible. It seems their design is centred on guaranteeing that the drugs remain uncompromised and are created with rules and regulations in mind (e.g. the linguistic register used on the package insert) than built around users' experience, in line with their physical and cognitive characteristics.

For the power that the scientific world bestows upon them and the social role that drugs assume rhetorically, their prescriptive shapes have not attended to finding an appropriate expression for "generating inclination" or empathy towards treatment regimes. They speak to their author, heedless of the users' cultures or the emotions that accompany illnesses and the restrictions their treatment imposes. They don't offer feedback, which might reassure users that they are taking the correct action. Neither do they contain auxiliary advice for patients, to allow them to frame their pharmacotherapy within the wider picture of their hygiene and nutrition regimes, or that of an ideal lifestyle. This is isolating for an ill or injured person, creating a sense of otherness out of their condition.

3. A drug's meaning as a symbolic object: new paths for investigation

We dwell on a paradox, going only so far as to raise that paradox as a further path of study. It concerns objects and their functional, signifying and symbolic value. The form of objects and their requirements as tools can be reabsorbed into a circle of meaning that lies without or goes beyond their use (Barthes, 1974). This hypertrophy of meaning (Landowski & Marrone, 2002) makes an object's dimensions as a tool-less natural and obvious, through the socio-cultural meanings attributed to it (Baudrillard, 2007).

Objects seduce, becoming iconic and memorable. They amass affective and emotive values. They become an obsession, in the sense that we project our imaginations, fantasies and intimate dreams onto them (Dorfles, 1988; Fusillo, 2011). However, objects also have a mythopoetic strength, when portraying the widespread cultural values that society incorporates into them (Barthes, 1974).

And that is how a drug exists not only within its specific role but also by having amassed a deep symbolic dimension, because, by curing illness, drugs become an impediment to the link between life and death. Our imaginations use specific vocabulary to evoke the sense that the active ingredients contained in drugs defeat illnesses—attack, kill, beat and fight off. Such vocabulary belongs to mythological tropes which we project onto these objects (Barthes, 1974).

3.1 Drugs as communicative objects

Communication intervenes in this construction of functional and metaphorical value, with its graphic and textual *paratexts* (Genette, 1989). We find them on the objects themselves (*peritexts*) in the form of the information on the packaging or on the package insert. But we also find they reappear far away from the objects (*epitexts*), in user comments, in online chatter, in advertising messages, in marketing reviews, in scientific bulletins, etc. For drugs, however, the communicative-identifying component and the informative-prescriptive component, have peculiar rationales. The nature of products, the need they respond to, the users they target, their methods of sale and purchase, and the circumstances under which they are used, all come into play here.

Moreover, drugs are part of a hyper-regulated world where every form of design revision requires a cultural development, experimentation and consultation. All of this collides with policies created above the industry level. This world is struggling; it's far behind in the process of reconverting information into digital records. It's held back by an ageing population - the primary users of pharmaceutical products - reluctant to move away from traditional information sources.

It's within this context that we have been unable to build a peritextual and epitextual information system for communicating the legendary benefits of pharmacotherapy and the epic progress made by research and its findings. Such a system could raise awareness, warn, inform and create a culture of "good usage", warning against the ease of excess, *Do It Yourself* (DIY) regimes, irresponsible usage and "hearsay".

3.2 A drug's peritexts

As for the vast system of information - peritexts - on packaging and package inserts, we find ourselves faced with forms of communication whose arduous task is to explain complex procedures. These explanations suffer issues relating to the translation process (Nergaard, 1995; Osimo, 2015; Baule & Caratti, 2016) and, specifically, to what they are required to explain by way of text descriptions: actions, gestures and procedures, often involving components of tacit knowledge (Polanyi, 1979). These prescriptive forms also suffer the issue of inert denotation (Sennet, 2009), a form of writing in which the language, mode of expression and type of information are only comprehensible and useful to an expert user or one who already has experience with such procedures.

Finally, these texts present a strong imbalance between negative descriptions of the side effects drugs can cause compared to their benefits. The latter is reduced to a few lines. There is no counterbalance to the long lists of side effects that reference data on each drug's effectiveness at reducing or eliminating the symptoms of illness would offer. They don't take care to provide consoling descriptions of the signs that would signal the desired wellbeing.

4. Actions taken into account when designing drug shape and user experience

4.1 Some Problematic Points

Here we propose various questions regarding drugs' nature in relation to certain theories about objects and the rationale behind their relationship with end-users. There are some peculiarities worth noting:

- It's difficult to understand drugs as objects for use and to align them fully with opinions or reflections on drugs (Pizzocaro, 2016). Even with the huge range of medicine shapes, attention to formal aspects and their ability to evoke their required function seems weak. Drugs seem to (provocatively) boast a total absence of formal elements, sensorial activators and indications for use. These are necessary elements for bringing users and objects closer together, through understanding, organisation, gestures, interaction, memory, etc. In the pharmaceutical world, we settle for working with the shapes most like the things we normally consume (e.g. food). This juxtaposition doesn't leave space for attention to be devoted to gained or learned sensorial experiences, cognition, rituals or the gestures that we see with nutrition. That makes the action a truly cultural act, accompanied by training in *techniques of the body* (Mauss, 1936) learned by experience.
- It's difficult to categorise drugs fully as objects for consumption. There is a vast literature behind the dynamics that generate needs and then allow objects to meet those needs. This comes from market research, the psychology and sociology of consumption, human ethology and even psychiatry (Fabris, 1970; Pizzocaro, 2015). Studies on purchasing behaviour, possession and consumption of objects are vast and able to quell desires and align with physical, mental, natural and cultural needs (Fabris, 2003). Yet, even in this category, it's not easy to find a place for drugs. Experience of health and illness comes down to personal experience, but it's also a cultural construction. And even with different sensibilities, we attribute great importance to wellbeing and health only when deprived of them (Borgna, 2005). Only then do drugs enter the needs category: not as a desirable product, but as a remedy, something palliative. Once introduced into daily usage, we are aware they are missing only when we find ourselves without them. It's never the user that chooses the drug but a professional. Here we pose another interesting element in terms of drugs as objects: needing them, choosing them, methods of using them that require technical skills which users ask from expert figures.
- And finally, despite attributing drugs with the typical prerogatives of objects used daily, we observe that anything we consider positive in the behaviour of using drugs in the home becomes a potential source of error when applied to drugs.

4.2 Otherness experienced by users undergoing treatment for chronic pain

A drug is part of a process - of treatment - connected to macro-systems (science, technology, the industry) and micro-individuality (the patient, the familiar context of treatment). This process, especially for chronic conditions, can meet with new feelings of otherness. Now that people live longer, expectations of living independently are falling, leaving a population vulnerable to pain (Scheler, 1916). We feel the effects on body and mind because “pain breaks. It’s the division” (Heidegger 1959). Illness induces a change in the world of life, to the approach towards the other, transformed in terms of its functions and abilities. Drugs leave traces, they mark the body. They act as a form of apparatus, called upon to reinvent a new order of space and time, defined by the procedure-based nature of the treatment, that breaks up individual, familial and domestic space. New objects enter into daily life: drugs, prescriptions, diagnoses and treatment plans find a place along surfaces to which cognitive and aware minds assign positions. Those positions may be functional, they might be symbolic or moral, or perhaps they are dictated by previous experiences.

Tangible and intangible variables (skills, places, objects) insert themselves into the ecosystem of treatment. They can be read only within the framework of their relations. The same medical narrative (Morsello et al. 2017) recognises the value of sensitive reports underlying the ability to narrate and to recompose old and new experiences through reconfiguration processes.

4.3 Adopting a human-centred approach for the experience of using a drug

In developed countries, populations have longer life spans, thanks to better access to treatment opportunities and the use of drugs, but with a significant economic and social cost. What is more, the context of treatment is changing, in terms of its location and physical dimensions (moving from hospitals to homes) as well as in terms of its organisation (greater accountability placed with the end-user). This represents an opportunity to redesign care systems so that they are human-centred and involve the subjects. This means intervening in how objects are presented and communicated, and in changing service, systems, usage contexts and activities.

The elderly has been prioritised as a reference point for design on account of their personalities, physical and cognitive attributes, and linguistic barriers linked to their health literacy. Delegating responsibility for treatment management to such users presupposes their active involvement, an education suitable for the language of the treatment, making it comprehensible and checkable even at the point of dialogue between specialist and patient (Graham & Brookey, 2008) and for their interaction with the products and tools that support treatment. Within the context of “domestic independence”, the latter should be functional, usable and even pleasant to use.

It should be noted that users allow themselves to interpret objects (especially those with no social protocols or where uses are not embedded overtime), sometimes generating more meaningful alternative uses that have a social influence on the intended use (Pizzocaro, 2015). Conversely, the use of drugs is situational and not necessarily permanent. As such, the same users find themselves without defined use strategies: on the one hand, they try to understand and adopt suggestions from the doctor or package insert; on the other hand, they mutate and apply usage models from other product categories (Norman, 1988) that they are used to following.

In the world of drugs, learning by drawing similarities with actions used for other objects - where experience of use cannot distinguish errors - poses an objective risk to user-health. The spurious passage from novice to expert and excess confidence is among the most frequent causes of drug management mistakes. Perhaps the perceived distance between drugs and other product categories is so reduced - due to familiarity, habits or marketing and advertising for products that are consumed on a daily basis - that users are induced to use them without knowledge and erroneously.

Above all, elderly users might be kept safer if they are correctly informed or interact with objects they understand - objects designed not only to treat but also with consideration for the drug management process (Graham & Brookey, 2008), with adequate checks on their actions. Guiding and influencing user behaviour during treatment - by redesigning the drugs and the objects connected to them - is the designer's role. That can happen only with an understanding of the true physical, cognitive and social capacities of the users, by involving them as we perform the design development process for products/services so as to improve the experience of use, as we seek to prevent the errors that have occurred in the design and use of objects for some time.

5. Conclusions: aiming for practices involving drug familiarity

We would like to list some examples of certain characterisations of people's behaviour when undertaking daily tasks, believing that it's useful to lean on these when developing our design considerations for treatment processes.

- Familiarity. We can consider familiarity as a complex cultural system where the following coexist: forms of reciprocal adjustment, lexical constructions and behavioural jargon, shared images of health and illness (Santambrogio, 2006), the learning of techniques and adoption of tacit knowledge, the development of discretion and sentiments about the body and its treatment (Foucault, 1985; Pennac, 2012), the experience of public and private forms of illness, the influence of beliefs (including religious beliefs) and of ideologies concerning space and objects and their uses. Familiarity immerses us in an "experiential realism" where each individual linguistic, lexical and behavioural element has overlapping

emotional and value-based meanings. They can be interpreted as cognitive data and various forms of knowing how to do something (Maher, 2014, pp. 8-9). In the realm of familiarity, we focus on systematic indices of thoughts and actions more or less consciously. Gradually, as correlations between these forms are strengthened, the framework of associated ideas ultimately becomes a way of measuring normality (Kahneman, 2011). Finally, everything that we consider familiar - and therefore normal - is part of a sort of "base-level knowledge", which encourages us to subtract every individual action from the process of conscious reflection. Familiarity legitimises the transfer onto a drug and the treatment it provides of habitual regimes (acquired from using other objects), of the ways in which we interact with them, and of the rationales under which we bring them into the domestic space, etc.

- Habits. These are a constituent part of familiarity, of domesticity. This is the prerogative that, beginning with the concept of habitus (Bourdieu, 2001), injects our actions into "a system of perceptual, ethical or aesthetic ways of thinking and actions acquired over time". They tend to endure even after a change in the conditions that generated them (Bourdieu, ibid.).
- Repetition. Treatment regimes, repeated daily, become habitual, and therefore practical methods, gestures and knowledge are fortified over time. However, they are by and large self-learned. There is a transition from novice to expert when learning to use any product, but with drugs, there is vast scope for error and misunderstanding. Further, an absence of solid knowledge precludes users from exercising their own discretion, interpretation and therefore good sense, as the rationales underlying drugs and their consumption don't belong in that sphere of common sense (Santambrogio, 2006).
- Confidence. This falls under the possible disintegration of what we have called familiar behaviour, lingering in this last case on lax behaviour, ease of distraction, shortcuts to simplify prescriptions, and DIY solutions improvised by users when they believe they have sufficient understanding about how a drug is administered. Generally speaking, this trust in their actions is supported by the positive outcome of actions repeated over time. It can become an obstacle where, even with repetition, one causes the kind of accidents that typically result from "homemade" actions, which are never uniform and always require the problem, context, objective and treatment action to be rethought from scratch each time.
  And it's here that the tangible and intangible essence of apparatus and its prerogatives (as mentioned earlier) to "capture, orient, determine, intercept, control and safeguard human beings' gestures, conduct, opinions [...]" (Costa, 2016, p. 75) could become prime exploratory territory to guide the processes—which increasingly rely on technology—for managing pharmacotherapy.

The Wicked Home: Living Space as Ecological Holobiont

Abstract | This paper discusses a new culture of life through architectural design at a time of ecocide. Establishing the principles of practice for an ecological era by reconfiguring the terms of our engagement with the living realm by de-anthropocentrising the human self and embracing the liveliness of our environments, the way we inhabit spaces is reimagined through the infrastructures that inform the rituals of everyday life. Inspired by the irreducible complexity of the living realm, the Wicked Home research project discusses an approach that increases the liveability of our homes by nurturing many nonhuman "others" without compromising the quality of life for humans. Entangled with an ethics of care, these design principles are exemplified in the *Living Architecture* and *Microbial Urbanism* projects, which discuss how such proposals can be realised in practice.

KEYWORDS | HOME, DE-ANTHROPOCENTRISING, WICKED, CARE, DESIGN

1. Introduction

What would it mean to de-anthropocentrise our concept of home? If we eliminate the metaphors of appropriation, ownership and occupation alongside the so-called Activities of Daily Life of the human, how might we reconfigure our need to communicate with the liveliness of our environments?

“Conversation with a Stone” by the Polish poet and 1996 Nobel Prize winner Wisława Szymborska provides one approach. The poem is frequently read as an epistemological cul-de-sac; the poet wishes to know every detail of the external world, but the stone remains shut, not accessible to human experience and inquiry. The poet’s repeated request to “enter your insides/ have a look round,/ breathe my fill of you” is consistently refused by the stone, whose pronouns are capable of switching mid-sentence from singular to plural in response to external violence, while still speaking with one accord—“I’m shut tight./Even if you break me to pieces,/we’ll all still be closed./You can grind us to sand,/we still won’t let you in.” The stone continually points out the epistemological incommensurability between the poet’s embodied, sensory knowledge and its own material form (“I'm made of stone […]/and must therefore keep a straight face.”). Neither curiosity, imagined palaces nor bathetic appeals to the poet’s mortality grind down the stone’s resolve (“Go away./I don't have the muscles to laugh.") This means that the epistemological terrain from which each speaker addresses the other does not even meet, let alone overlap. If we assume that each even hears the other (although the evidence in the poem for such an optimistic assumption is debateable), there is nothing to suggest that one is speaking from where the other is hearing. The poem therefore presents a hermeneutic dead zone, a space characterised by an absence of dialogue and resonance:

> “You may get to know me, but you'll never know me through.
> My whole surface is turned toward you,
> all my insides turned away." (Szymborska, 1997, p.63)

In the fourth exchange the poet brings all the powers of human persuasion to the task, describing the proposed visit as being only temporary, motivated neither by unhappiness nor homelessness. The poet has a world “worth returning to” and will “enter and exit empty-handed”, recording the entry into the stone only with “words,/which no one will believe”. This provokes the stone’s most scornful response:

> “You shall not enter,” says the stone.
> “You lack the sense of taking part.
> No other sense can make up for your missing sense of taking part.
> Even sight heightened to become all-seeing
> will do you no good without a sense of taking part.
> You shall not enter, you have only a sense of what that sense should be,
> only its seed, imagination.” (Szymborska, 1997, p63)

It is a remarkable inversion of anthropocentricism that the stone should here tell the human "You lack the sense of taking part." Furthermore, "No other sense can make up for your missing sense of taking part." The stone effectively reveals itself to be more empathetic and insightful than the poet. Another 'natural order' exists, it seems, to that we thought we knew.

In the final stanza the stone refuses poetic conceit altogether, bringing thereby the poem to an abrupt end — no 'accommodation' is reached, poet and stone remain implacably 'alien' each to the other:

> I knock at the stone's front door.
>
> "It's only me, let me come in."
>
> "I don't have a door," says the stone. (Szymborska, 1997, p64).

The poet's techniques—reflection, imaginative empathy, inquiry—are ultimately shown to be inadequate to the task. And yet the poem does not mock such attempts to connect. Language itself can be said to constitute a threshold or portal—that poet and stone are able to exchange requests and refusals shows a protocol is possible, one that permits the exchange of perspectives and positions, and this ultimately transforms what could have been a mute meeting between incommunicable subjectivities into an encounter with epistemological humility, empathetic agility and rigour, and the duty to engage actively with that which we study.

This *politics of participation* can be said to inform the thinking behind the current paper, which calls for profound changes in attitudes to the concept and reality of *home* via a domestic ecology in which the human inhabitant exits the stage, and other, nonhuman, agencies are instead invited into the spotlight. What the authors propose is a concept of home as a constructed form of nature—specifically, *a wicked home*. To get there, we must facilitate conversations between things and agencies that are usually either kept apart, or rendered mute under the looming shadow of the human.
In the following we will explain how a wicked home could be constructed and why we believe it should be constructed. Two interconnected tracks run parallel through this paper, shaping our argument. One is the motive—what sets us in motion, what urges a shift. The other evokes the possible new constitution of home—what it is made of, what it lives by. These tracks present us with emerging design challenges—collectively, they represent a *wicked* design challenge, one that architects need to address with some urgency if they are to respond to the demand of architecture students for meaningful change to the damaging impact our present industrial approaches and toolsets are inflicting on the environment (Architecture Education Declares, 2019).

2. Design at a time of ecocide

Wicked

At a time of ecocide, **a *culture of life*** must enter into an age of ecological design, where our toolsets for perceiving, conceptualising, theorising, designing and modelling our world are concordant with the ethos of (re)enlivening. To date, the profession has responded by devising ecologically "kinder", or more "sustainable" versions of existing practices. Such inaction is less cognitive dissonance than a failure of imagination to inhabit different stories about our relationship with nature and culture. Such naturecultures are the very milieu in which we exist (Haraway, 2003). In taking our first steps towards an ecological era, we must develop new types of design, the principles, materials, toolsets and expressions of which may not even be recognised by today's standards.

A first step is acknowledging that the term "ecology" is ontologically problematic. Arising from a utilitarian view of managing nature, the household of god, Enlightenment scientists, proposed an "oikonomics" of the environment (Linnaeus, 1749; Hestmark, 2000) and animal management (Haeckel, 1866). Fundamentally imperial, it was transformed during the 20th century (Anker, 2001), into a mechanistic, land management view of "ecosystems", then a totalising concept of earth as a colossal self-regulating cybernetic system, proposed by the Gaia Hypothesis (Lovelock and Margulis, 1974). By the late 20th century "ecology" was implicated in all interacting "systems", relationships and

Home

IMAGINE a building infrastructure that houses microbes that perform useful domestic work such as cleaning water, making useable amounts of electricity and producing a range of metabolites, which are fed back into the household system or released to enrich the natural environment. Aiming to wean modern homes off their dependency on fossil fuels, it provides microbial strains with ideal environments for flourishing, where they are made to feel "at home" by feeding them regularly and providing them with a safe environment to build microbial settlements. The microbial "brain" that processes the biochemical information and productive fabric, or "flesh" that carries out the complex biochemical transformations, is a bio-electrically active anaerobic biofilm—something like the gelatinous sludge found down the U-bend of your kitchen sink or toilet—which is housed within a ceramic battery casing. Feeding on nutrient streams of domestic waste that pass into its stomach, or anode, a low-pressure stream of water and biomolecules pass through its "gut wall", which take the form of a carbon fibre, or ceramic semi permeable membrane. The waste products of these cyborgian microbial transactions are electrons, or quantum excreta, that self-power the system and are captured by conductive wires, optimised by an artificial intelligence, and visualised through the activity of electronic devices. Other effluents take the form of cleaned water, or "bacterial urine", while a further range of organic substrates pass through the semi-permeable membrane into the cathode, or "bladder", ready for discharge. While much of this domestic work is invisible to humans, electronic sensors convey microbial actions via a digital interface,

non-living structures, including geophysical forces, materials and cities (Harvey, 1996). Ecological thinking's evolving epistemologies have led to increasing debates about the appropriate expression for 'life' within a world in the throes of ecocide. In generating "straightforward environmental images" (Morton, 2007, p150) Timothy Morton uses "ecology" to replace bucolic visions of "nature" with an equally problematic "dark" ecology that depicts an irredeemably contaminated world. Such re-aestheticisation overlooks human responsibility for our damaged ecosystems. The colonialisation of thought that characterises human exceptionalism and frames our anthropocentric worldview, means we cannot fully acknowledge or address the many other agents that co-constitute our world. While inherently problematic, "ecology" also lends itself to new conceptions, which are shaped by the rise of post-humanism in late 20th century and advent of new materialism at the turn of the 3rd millennium. Embracing a *more-than-human perspective*, alternative ecological narratives enable different kinds of power structures, transactions and relationships by elevating the status of all forms of empowered matter—living, biological, agentised, reactive, vital—from their dependency on human relations. Free to produce effects and exist in their own right through a condition of mutual care between actors (Tronto, 1997), they constantly negotiate their position and relevance to the living world.

This ***new culture of life*** re-purposes the familiar tools of modernity and makes visible the other worlds it has ignored and which enables conversations between human and nonhumans to generate a quality of interdependent living that is powered by domestic waste streams. Further incorporation of technologies such as screens and robots that feed on electron flows, comprise a specific *metabolic trading system*, where the overall *housework* performed is meaningful to all participants.

The strange substrates and infrastructures described here are the results of the Horizon 2020 funded project *Living Architecture*, co-developed by the Experimental Architecture Group, who picture a "Home" as a holobiont, a designed form of nature where 'speaking' chemically, physically, biologically, mechanically and even digitally (through electricity) with the nonhuman realm becomes possible, transforming our activities of daily living into world-making actions.

Inhabited through rituals of care and nurturing, Living Architecture provides an apparatus that exemplifies how homes constitute entire 'worlds', or experiences in themselves, presenting alternative paradigms for domestic economies, and the potential to bring about integrated, systemic change in the material impacts of human inhabitation that contribute to planetary enlivening. When we design and inhabit our homes in this way, we become holobionts, being composed of wholly integrated assemblages of different species, microbes, humans and technical agents that form coherent units capable of performing useful work, and which do not discriminate between their matter and excrement. Those living spaces that thrive on entangled relations produce the infrastructures for Wicked Homes. How a home could be constructed from a posthuman household inhabited only by microbes and the digital ghosts of the past, present and future was prefigured in the

damaged. Specifically, it calls modern conceptions of biology into question, which entered into common language at the turn of the 19th century. Increasingly professionalised and specific, the term "biology" was independently introduced by scientists Thomas Beddoes, 1799, Karl Friedrich Burdach, 1800, Gottfried Reinhold Treviranus 1802 and Jean-Baptiste Lamarck, 1802. Referring to a particular quality, or kind of life, "bios", this new field became increasingly specialised and produced further new disciplines like plant and animal physiology. During the second half of the century, the laws of thermodynamics shaped biological narratives, where physiology was underpinned by basic energetic and metabolic exchanges like photosynthesis and respiration. Over the course of the 20th century, these new disciplines sought to understand the mechanisms of life, becoming further componentised into cellular, and molecular biology. Having reached a pinnacle of ultimate control over the very building blocks of nature, the late 20th century witnessed our ability to re-write the book of life through DNA sequencing. Approaching a point where meaningful changes to the way an organism works need to be situated, Andrew Ellington observes "… context matters, the system matters, the background matters. Which is all about how things are going to interact inside of an organism. It's not just an isolated pathway, it's a pathway inside an organism. And so really, we're coming around from pure design to design in the context of the system, which is more systems biology" (Ellington, 2015). Using mechanistic frameworks to conceptualise installation *999 years, 13 sqm (the future belongs to ghosts)*, a collaboration between Cecile B. Evans and Rachel Armstrong, 2019, projecting a way forward through which the transformation towards our emerging ecological era can begin.

While such "lived" systems are discrete worlds, their persistent exchanges may also constitute lively infrastructures capable of spilling out beyond the boundaries of a traditional house interface and leak into other associated realms of care such as the street, the garden or public square. *Microbial Urbanism* (MU) builds upon the "programmable" microbial exchanges underpinning the Living Architecture project and scales them up to an urban scale. Through the first-time convergence of two established microbial platforms—arrays of organic batteries, or Microbial Fuel Cells and root microbiomes that take the form of "functional" wastewater gardens—MU provides an urban infrastructure that *generates carbon-free electricity directly from wastewater*, which is contaminated with human, agricultural, or industrial waste. Sharing the same wastewater and biowaste stream inputs, these combined technologies directly couple organic processes with high tech "smart" solutions, thereby providing sustainable energy from urban biowaste that powers digital services and can be thought of as a "bio-digital" platform. A MU pilot project is proposed for Tallinn, with site evaluations also taking place across different European municipalities. Overall, the project's ambition is to catalyse bio-digital platforms that integrate the resource streams of physical (organic) and virtual systems to reduce consumption streams, as well as bringing about the widespread establishment of culturally diverse bio-digital cities. Collectively and individually, MU's

these "BioBricks" (Tom Knight, 2003) emphasised the difficulties of their re-assembly by synthetic biologists and the processes of life were deemed irreducibly complex—a "wicked" challenge. Evelyn Fox Keller observes the non-innocence of the gaps in our understanding: "Whose law is the law of nature? Where does the idea of a law of nature come from? And what is the function of a law of nature? The law of nature, the concept of a law of nature comes originally from the civic realm" (Keller, 1990). Recognising the missing pieces of life's mechanistic puzzle as "zoe"—or "bare life—Rosi Braidotti calls for concrete gestures that value this animating force through all its manifestations (Braidotti, 2006, p41). A new biopolitics and biopower (Foucault, 2004) challenge existing governance, classification systems and other modes of subjectification, including identity politics. Their impact on unacknowledged nonhuman subjects is devasting and manifests as global ecocide. Recognising the vital couplings that occur between nonhuman bodies, brings forth an *alterbiopolitics* of care, from which a *sympoietic* order of "labour/work, affect/affections, ethics/politics" arises (Puig de la Bellacasa, 2017, p.5). This new politics between human (bios) and nonhuman (zoe) does not take place in the oppressive manner through which Hannah Arendt regarded "bare life" in the public realm, as denying a person the possibility of a political existence (Arendt, 1958, p98), but through Giorgio Agamben's conception, where a new system of power relationships is possible (Agamben 1998, p.13), comprising a "good" quality of existence for all. Freeing lively matter from activities seek new paradigms, concepts, platforms, toolboxes, services, products and experiences, which can be networked to establish foundations for new kinds of community transactions that work towards enlivened, regenerative bio-digital settlements hosting many kinds of Wicked Homes. Through a spectrum of such prototypes, the development of Wicked Homes seeks to establish transferable principles, an ethics of practice that enable an 'ecological' approach to the production of our living spaces, and our first, tentative design steps towards planetary enlivening.

The projects Living Architecture and Microbial Urbanism draw together the concepts of ecology, Zoë, the decentred human and *agentised "household" of nature.* They provide a framework for a radical re-enlivening, a re-conceptualisation of what it means to inhabit a world at a time of ecocide. How this impacts and reconfigures design practices becomes the topic of a recently established Academic Design Office (ADO) at KU Leuven. The Wicked Home ADO takes a radical break from modern architectural practice and considers the character of our homes as irreducibly complex, a variable and contingent synthesis between infrastructures, inhabitants, materiality, context/site, technological interfaces, and the concerns of the architect—in other words, they are "wicked" spaces. Modern architecture, however, prefers to enliven machines using industrial scale energy sources that simplify complex organic resources into electrical power supplies. At the same time, when inhabited, the buildings discard (complex) waste matter into the 'environment', spending as little time as possible within our living spaces before they are discarded through drains, vents and garbage disposal mechanisms. Denied any chance of a meaningful 'living' existence through recycling, re-use or

the obligation to mimic biological systems as the authentic operating systems of life, an expanded view of the living realm can be considered from first principles, namely; materiality, agency, ethics and infrastructures. Fundamentally messy, sticky (clinging to other bodies), irreverent (not obeying conventions) and semi-permeable to their surroundings, these vital agents constantly seek new alliances, and embrace ongoing change by continually responding to their context. Unleashed as all kinds of "unholy" matter, protocells, "living" gels and other monsters defy our understanding of matter, waste, technology, life and body, overturning the recognised order of the world.

"And now the plants can no longer be distinguished from the animals. Polyparies, which have the appearance of sycamores, carry arms on their branches. Antony fancies he can trace a caterpillar between two leaves; it is a butterfly which flits away. He is on the point of walking over some shingle when up springs a grey grasshopper. Insects, like petals of roses, garnish a bush; the remains of ephemera make a bed of snow upon the soil." (Flaubert, 1981, p231)

Recognising these blasphemous assemblages as "contradictions that do not resolve into larger wholes, even dialectically, about the tension of holding incompatible things together because both or all are necessary and true" (Haraway, 1991, p5), Donna Haraway proposes the political myth of "cyborg", which occupies the treacherous realm of fiction and social relations uncoupled from organic reproduction. While Haraway's cyborg

molecular transformation, our effluents become 'waste'. Advancing how our built environments are designed, constructed and inhabited, the Wicked Home engages our own metabolic activities (consuming resources, producing waste matter, moving around) within our living spaces and entangles our daily activities with the natural realm, where the flows of air, water, natural resources and the activities of daily life complicate the notion of what it means to make a 'liveable' habitat.

By critically engaging experimental frameworks and practices, the Wicked Home expands the limits of design practice through inter-, trans- and post-disciplinary explorations, using speculative design, prototyping and critical projections. Grounded both in solid theoretical frameworks (new materialism, post-humanism), as well as transformative practices, these concerted actions fully engage with the design of lively substrates. While expanding the realm of human action and acknowledging the participation of nonhumans, the wicked home remains "homely", inviting the delineation of a domestic ecology (oikology) in which the human inhabitant plays one of many parts. Conceiving the "home" as a coherent world comprised of complex, quasi-living bodies, it offers a counterpoint to modernity's concept of machines that still find favour within the field of architecture. Recognising their inner life of nonhuman things, as well as our interdependencies, the Wicked Home is an experimental platform for drawing together multiple forms of knowing that are not exclusively human. Conferred with the status of 'nascent beings' which symbiotically work alongside us as an immersive, evolving choreography of space and matter, the Wicked Home incorporates a wide spectrum of wicked matter (inanimate, human, vitalised, biotechnological) that is

circles its relation between animal, human, machine, a radical de-anthropocentrisation of its politics extends its influence into our proximate landscapes. Not backdrops for the actions of agentised assemblages, the nonhumans that make up our environment like soils, mycorrhizal networks and bacterial biofilms, form lively associations that configure the selective pressures acting on our bodies and also *become us*. Read through the interconnections and entanglements that shape the relations between all bodies – be they environmental agents, vital materials, technologies, metabolisms, or beings— Charles Darwin's identity dance between organism and niche, becomes a holobiontic state of affairs (Gordon et al., 2013). Navigating such turbulent spaces invites participatory modes of design and an ethics of practice where human and nonhuman are mutually co-constituted, and the notion of what it means to be a body, or living being of any denomination, is radically expanded. Making obsolete any conception of a "pure" human subject at the centre of design, holobiontic subjects (human and nonhuman) take the place of the *anthropos*, compelling us to understand what kinds of other lively agents we live alongside, recognise their diversity and pay attention to how they behave in different settings. No longer separate from the natural world, or our technology, we are co-dependent and entangled with myriad presences, within *a new culture of life* that welcomes unconventional states of existence and modes of design *as integral to its becoming*.

brought into proximity with other agents to forge enlivening interactions and thereby increase our co-responsibilities. Acknowledging these nonhuman presences through the organisation of our rituals and activities of daily life, the design *pursuit of re-enlivening* acquires a new empathy with the material realm and catalyses *a new culture of life* that re-engages with the critical issues of our time. Such an attitude generates a condition of care and attention for nonhuman beings that makes it nonsensical to abuse the spaces we inhabit, since they are part of ourselves. Framing our design interventions through an alter-biopolitics and *alter-oikonomics*, our attitudes to the concept and reality of *home* are transformed.

3. Towards a new culture of life

This paper is intended to outline a potential toolset towards creating a new culture of life. Without an effective precedent signposting the milestones to an era of ecological design, and lacking the appropriate concepts and methods, that enable us to fully participate in planetary enlivening, the way forward is challenging. Just as engineers building the first steel bridges without fully understanding the tensile properties of steel used dovetail joints optimised for wood, we too are caught in a twilight zone of uncertainty, transitional thinking, and incomplete knowledge of the optimum approaches. Only hindsight can tell whether the decisions we make are appropriate for the issues we seek to address. This does not, however, imply that we stumble forwards haphazardly, but instead continually assess our pursuit of (re)enlivening and what it means for design in the context of an emerging ecological era.

About the Authors:

Rachel Armstrong is Professor of Experimental Architecture at Newcastle University and visiting professor at the Faculty of Architecture, Campus Sint-Lucas Brussels and Ghent, KU Leuven. She pioneers the interdisciplinary field of “living architecture” that engages the material and technological potency of life within spatial agendas.

Rolf Hughes is Professor in the Epistemology of Design-driven Research at the Faculty of Architecture, Campus Sint-Lucas Brussels and Ghent, KU Leuven, and director of artistic research for the Experimental Architecture Group. An interdisciplinary artist and performer, his writing spans creative and critical genres.

Nel Janssens is associate professor and campus chair at the Faculty of Architecture, Campus Sint-Lucas Brussels and Ghent, KU Leuven. She co-founded (with Annelies De Smet and Jo Liekens) the Wicked Matter research platform that aims to radically question the agency of matter and materiality from an architectural perspective.

Acknowledgements: ROME Acknowledgements

The *Living Architecture* project ran from April 2016 to April 2019. Funded by the Horizon 2020 Research and Innovation Programme under EU Grant Agreement no. 686585, it brought together experts from the universities of Newcastle, UK; the West of England (UWE Bristol); Trento, Italy; the Spanish National Research Council in Madrid; LIQUIFER Systems Group, Vienna, Austria; and Explora Biotech, Venice, Italy.

The Wicked Home, Architectural Design Office at the Faculty of Architecture, Campus Sint-Lucas Brussels and Ghent, KU Leuven, is a traversal academic project that combines design practice, design education and research is led by Nel Janssens, Annelies De Smet, Jo Liekens, Laurens Luyten, Rachel Armstrong and Rolf Hughes.

The Exper*imental Architecture Group* (EAG) was founded in 2017 at Newcastle University by Rachel Armstrong, Rolf Hughes and Simone Ferracina to bring artistic and design-led experiment into juxtaposition with the technological repertoire of "living technologies". Fundamentally transdisciplinary and collaborative, EAG's outputs have ranged from written texts, to public installations and immersive environments.

The 999 years 13sqm (the future belongs to ghosts) bioengineering team comprises: Ioannis Ieropolous (lead; University of the West of England), Simone Ferracina (University of Edinburgh), Rolf Hughes (Newcastle University), Pierangelo Scravaglieri (Newcastle University), Jiseon You (University of the West of England), Arjuna Mendis (University of the West of England), Tom Hall (University of the West of England), Patrick Brinson (University of the West of England); MFC Bioreactor Brick Installation Design: Pierangelo Scravaglieri, under the guidance of Ioannis Ieropolous. Structure Design: Dominik Arni. Structure Fabrication: Weber Industries. Contributing Writer: Amal Khalaf. Animation: Tom Kemp. Music: Mati Gavriel. Three Dimensional technologies: Digitising Nature

Gregor MacGregor[a]

[a]Curtin University

Abstract | Digital technologies are changing they way in which we take, view and perceive images thus challenging our perception of the image as object, my research investigates how this changes our relationship with the subject object divide. Using emerging imaging technologies, such as multi image photogrammetry, we are now creating three-dimensional objects as opposed to two-dimensional images. This creates new ways in which the viewer can experience the image, more immersive and emotive, that is yet to be fully realised going beyond a visual record of objects. Through aligning critical discourse on perception and nature as well as exploring the creative potential of digital photogrammetry I aim to create multiple embodied experiences that challenge the viewers anthropocentric bias. With the aim of questioning the viewers preconceptions around the subject-object divide and exploring the potential that it can be used to narrow the culture-nature divide.

KEY WORDS | ANTHROPOCENTRIC, CULTURE-NATURE DIVIDE, PERCEPTION, PHOTOGRAMMETRY

1. Introduction

Through a reflexive studio based practice that involves a cyclical process of action/reflection (Praxis) (Adams, 2006), my research investigates the role that three-dimensional technologies, such as photogrammetry, can have in altering our perception of the object. Digital multi image photogrammetry, see Figure 1, is a process that has become affordable thanks to digital cameras. With increasingly powerful computers, a smartphone and open source software is relatively accessible, to non-professional operators. Digitising museum collections is already a well established practice, however this is mostly limited to two-dimensional photography, yet photogrammetry can offer further benefits, offering both scientific advantages as well as novel interactions for the non scientific observer. When a high-resolution digital camera is applied, photogrammetry can produce three-dimensional objects that are sub millimetre accurate as well as generating photorealistic textures. The primary advantage of this process is that it is non-destructive, the same as taking a

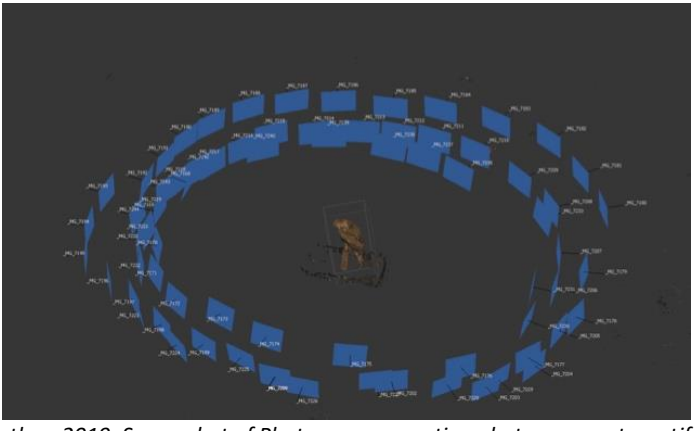

Figure 1. Author, 2019. Screenshot of Photoscan generating photogrammetry artifact.

photograph, but the digital object can be measured and handled, maintaining the integrity of the original artefact, as museum collections get older the original artifacts will become increasingly irreplaceable.

My research privileges the creative possibilities of this technology, over the scientific, and how this technology can be used to engage the viewer/subject in order to re-engage them with the natural world. The practical phase of my research has largely taken place within the storage facilities of the West Australian museum. In *Figure 2* we can see an example of the working environment, which illustrates that this process can be applied to multiple situations. This has provided me with the raw data (photographic images) from which the creative possibilities can be explored, the results of which will be explicated in the constructing a digital nature section.

Figure 2. Author, 2019. W.A. Museum storage facility, example of working environment.

By relating the process employed by natural history museums to the subject they deal with, it has allowed me to further align the research within existing academic debates on the culture-nature divide as well as the subject-object divide. The natural sciences and (western) society have been grounded in the traditional views on the subject and object since the times of Kant and Descartes. We, humans, observe the object and we gain knowledge through what we observe/perceive, whilst modern philosophy has been questioning this relationship between subject and object (Haila, 2000). The continental philosophers from the phenomenologists to the speculative realists have moved away from this Cartesian /anthropocentric point of view, however the traditional views are still persisting (Ben-Zeev, 1989). This research then asks, if the immersive nature of digital technologies can alter the anthropocentric bias that is inherent within the subject-object and culture-nature divides? Through investigating the creative potential of photogrammetry within museum design I aim to allow the viewer/subject to experience their relationship with the object. This practice led research will be supported by a theoretical discussion of the work of Maurice Merleau-Ponty (1945), Timothy Morton (2014) and Graham Harmann (2018).

2. Photogrammetry Intertwining the Real and the Digital

Whilst photogrammetry is not necessarily a new technique, the introduction of digital cameras and accessibility to powerful computers as opened up the possibilities for the applications of photogrammetry. Photogrammetry is the process of making measurements through the analysis of multiple overlapping photographs (McCarthy, 2014), refer back to *Figure 1*, it was originally used as a method to generate maps. They had a three dimensional, stereoscopic; depth to them and technology has made it possible to combine large groups of images rather than pairs. Digital photography has allowed much larger data sets to be used to reconstruct complex 3-dimensional models. As a result of the relative speed, low cost of the digital hardware and software multi-imaging photogrammetry has rapidly been adopted by archaeology and cultural heritage imaging (McCarthy, 2014). In archaeology multi-image photogrammetry is seen as a non-invasive method of measuring and researching the data rather than potentially damaging the original artifact.

One of the earliest applications of linking this technique, in the digital era, was the reconstruction of the Bhuddas of Bamiyan (*Figure 3*). These 40 metre high statues where destroyed by the Taliban, in Afghanistan in 2001, and photographs of the original statues where gathered from the Internet. Once enough images had been gathered from a variety of sources archaeologists where able to generate accurate 3-dimensional models that could be used to reconstruct the Bhuddas of Bamiyan, from the remaining ruins (Grun, 2004). Since then multi-image photogrammetry has become a standard part of the archaeologist's work practice (McCarthy, 2014), and has been integrated into the practice of digitising museum collections. For the most part this digitisation process is largely seen as a way to keep a visual archive of the collections. However constant technological innovations are reshaping the role of museums, changing the ways that they produce and distribute their collections (Bertacchini, 2011). Whilst three-dimensional techniques such as laser scanning are been used, the cost is, for all but the most well funded of institutions, prohibitive. With a reasonable digital camera, appropriate software and minimal lighting rigs, multi-image photogrammetry provides an affordable alternative. With an archive of ever increasingly accurate digital 3-dimmensional objects this opens up potential opportunities for creating interactive online museums and digital artifacts that supplement the original objects. This can also open up economic opportunities that arise from licensing the digital objects, although this is limited at the moment for research and educational purposes (Schweibenz, 2004).

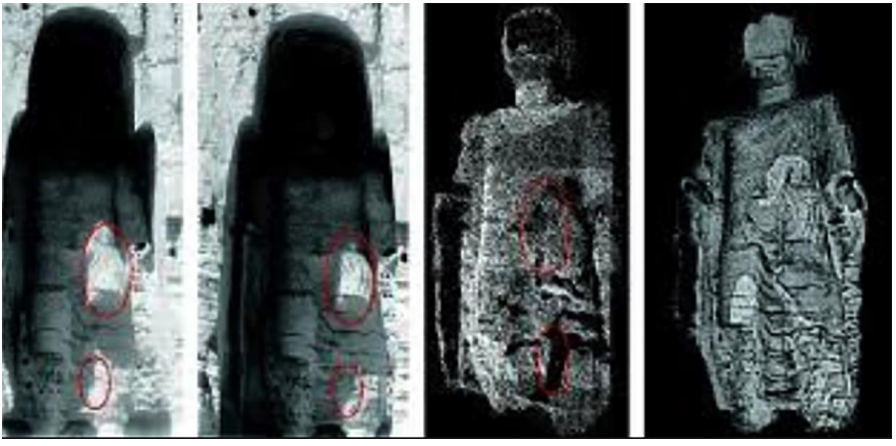

Figure 3. Armin, Gruen. 2004. Photogrammetric re-construction of the Great Bhudda Of Bamiyan, Afghanistan. Photograph and three-dimensional re-construction.

2.1 Museums and Technology: Digitising the Object

Traditionally museums have been seen as institutions that collected and preserved physical objects in order to produce knowledge (Bertacchni, 2011), their primary objective was to preserve and catalogue whatever objects they specialised in. They would then transmit the accrued knowledge to the general public as well as make the objects available for research (Alexander, 1983; Lewis, 2011). Museums in the late 20th century are often criticised for being elitist temples of colonial loot, and even as late as 1996 the historian Gyan Prakash proclaimed that museums themselves have become history (Thomas, 2016). Since then museums have reinvented themselves and continue to thrive, in part due to technological innovations this has reshaped the role of museums as producers of culturally significant content. The digitisation of museum collections, as well as increased capacity for digital storage and accessibility to the Internet, has changed the ways in which we manage and access information (Bertacchini, 2011). Opening up new ways to retrieve, experience and even monetise collections, it the experience of digital collections that I wish to privilege in order to analyse how we can engage with technology as opposed to the "real" world.

This leap from the physical object to the digital one represents a paradigm shift in the way we represent objects as images, even greater than the inventions of photography, cinema and television (Jeffrey, 2015). In order to better understand our relationship with the digital object it is important to acknowledge both the immateriality and the uncanny nature of digital images (see *Figure 4*). These digital reproductions still have similar issues of authenticity as analogue (mechanical) reproductions. "One might subsume the eliminated element in the term "aura" and go onto say: that which withers in the age of mechanical reproduction…" (Benjamin, 1968). The point that Benjamin is making is that reproductive media, such as photography, has a diminished sense of aura or presence compared to the

original object or artwork (Bolter, 2006). For the most part this stands for digital media, as it is still a reproductive medium. Digital reproductions, due to its ephemeral nature, still lacks a physical presence, an aura, perhaps the field of haptics may change this, for now the digital reproduction will still have a sense of the uncanny valley (Jeffrey, 2015). Whilst this creates a sense of separation between the subject and object as the technology improves, this separation will change, already the immersive nature of the technology is regarded as more emotive than traditional imagery and even the real object (Geismar, 2015).

Figure 4. Author. 2019. 3-D model of Hawk.

3. Dualist Dichotomies and the Anthropocentric Bias

To better understand our changing relationship with our perception of images generated by digital technologies it is important to understand some context between the subject-object divide. This section will include an overview of Descartes dualistic approach and the philosophers that consequently eroded this method. Western philosophy and the natural sciences have been shaped by the relationship between the subject and the object. This is largely as a result of Descartes theories between *res cogitas* and *res extensa,* a separation between the mind and body (Descartes, 1644). This separation of the subject and object has resulted in a dualistic approach that has acted as a determinant in how we see the world (Haila, 2000).

This dualistic approach has its limitations; in that it separates the human from the world around them, it does not take into account the fact that humans are a part of the world. One of the first philosophers to address the inadequacy of this Cartesian dualism was the phenomenologist Heidegger (Cerbone, 2006). Phenomenology is a field of philosophy that studies the structure of consciousness as we, the subject, experience the world from the first person point of view (Cerbone, 2006). It was Heidegger who introduced the term *Dasein* in order to explicate our individual human existence, of being in the world, thus exposing the insufficiency of the subject object relationship.

Other phenomenologists, Maurice Merleau-Ponty in particular, argued against Cartesian dualism in that he felt it was inadequate when it came to understanding that which could not be seen. This marks a significant move away from the established philosophies of the time namely the theories of Kant and Descartes whose empirical methods of observation are still embedded into the epistemological approaches of western societies. However for some this does not go far enough, as it does not address the anthropocentric bias inherent in our perception of the world. This is where Speculative realism takes up the current debate around "Object oriented Ontology" (Harmann, 2018). It is a relatively new philosophical movement that aims to end correlationism[1], and anthropocentrism. Whilst it draws comparisons with the environmental discourse of Timothy Morton (2016) it is often seen as anti-phenomenological. Speculative realists, such as Graham Harman (2018), see phenomenology as having a dualistic relationship between [2]Dasein and Being, which therefore still creates an anthropocentric bias. Harman and other speculative realists reject both traditional empirical (Cartesian)[3] philosophies as well as some of the phenomenologists more anthropocentric ideas. They place the same importance on things, matter and real objects, bypassing more traditional viewpoints such as phenomenal experience (Morelle 2012). This would have a fundamental change in the subject/object relationship and arguably a philosophical approach that starts to move away form a strictly anthropocentric view of the world.

The speculative realists argue that we as humans need to stop privileging our perception, our agency, over the natural world. As this has led us to a point where our anthropocentric bias has had a more negative than positive impact on our understanding of the objects that make up our environment. This is a point that has been agreed upon by environmental theorists, such as Timothy Morton, who has aligned himself with Harman's 'object oriented

[1] Correlationism refers to the belief that objects only exist through human minds and language; Morton (2016) refers to this as anthropocentrism in a philosophical form.
[2] The phenomenologist Heidegger uses the term Dasein to describe our individual human existence, excluding traditional assumptions and prejudices of Being thus recognising the indeterminate nature of the subject and object relationship.
[3] The term Cartesian refers to the traditional Western philosophies (primarily of Rene Descartes, 1596-1650) that have dominated the natural sciences. Regarded as being too empirical by most modern philosophical movements.

ontologists' (OOO) (Morton, 2011). If we accept that, as Merleau-Ponty argued, empirical observation can only get us part of the way to understanding the thing that we observe and that our observations are intrinsically limited through our anthropocentric prism. Then it is possible that our perception of the object is fundamentally flawed, a situation that has created the environmental issues that we are facing. Perhaps one way to overcome the issue is to redress the imbalance that we as humans have placed upon the subject-object discourse, by shifting the debate from the perception of the subject to one that is more Object Oriented. I aim to explore our relationship with, perception of, the object and the role that emerging three-dimensional technologies will have in this debate. In particular the changing role of museums from empirical intuitions that categories nature to places that we can experience the natural world, in ways that illicit curiosity and wonder.

4. Intertwining the subject-object and culture-nature divide

The subject-object dichotomy has entered into current environmental discourse, as a way of illustrating the issues (anthropocentric bias) that have led to the culture-nature divide, insofar that the parameters with which humans perceive nature has been defined by humans themselves. The language with which we use to attribute a definition of the natural world can never be neutral. It can be argued that the language that western society uses to frame our perception of nature has been framed within the context of Imperialism and colonial attitudes (Moore, 2017), which can be argued is at the root of the culture-nature divide (Haila, 2000). On the one hand we have early environmentalists, such as Henry David Thoreau (Schama, 1995) creating a romanticised vision, "in wildness is the preservation of the world". Implying that an untouched wilderness will provide an answer to the failings of an industrialised world. This romantic view of nature is in opposition to the more imperialistic/colonial approach to nature in that nature can be controlled through such means as deforestation, to make way for agriculture and industry. This would appear to help create a schizophrenic understanding of the meaning of nature and the natural world, leading in part to the current culture-nature division.

For the purpose of this article I will apply a more contemporary definition of nature in order to clarify the ambiguous definitions of nature. In Bill McKibben's *The End Of Nature* (1989) he argues that Nature (N) no longer exists, what he is referring to is a world where humans have altered every aspect of the natural world. This marks the beginning of the debate at to whether we are still in the Holocene epoch or are we in, as Crutzen (2016) suggests, in the Anthropocene epoch (the age of humans), this definition will be explored in more detail later. However nature (n) refers to a natural world in which humans are intertwined with.

It is argued that our anthropocentric understanding of the natural world has been framed within our own social (western) construction, that we understand nature through our scientific/empirical study of nature. This Cartesian approach can only reach so far; ontologically this has a finite point. A more phenomenological approach to our perception of

nature is required. This can go some way to bridging the subject-object, culture-nature divide that traditional Cartesian methodologies have exacerbated. A non- Cartesian approach to understanding the natural world would be one that is aware of our biological limitations of human perceptions (Synder, 1996).

The meaning of the natural world as Vogel (2015) suggests is ambiguous, this ambiguity has in part led to a human-nature divide and this divide has created a schism between humans in discussions as to whether humankind lives within the natural world or side by side. Current philosophical thought is moving away from traditional western philosophy that has a bias towards prioritising anthropocentric requirements over that of the natural world.

5.Constructing a Digital Nature

Natural history museums are currently in the process of digitising their collections, a vast project, in the case of the Natural History Museum, London (NHMUK) this involves around 80 million specimens (Paterson, 2016). Initially this process started with the lepidopteron (butterfly) collection, 181,545 specimens, and this pilot project is intended to develop an appropriate workflow. The data that is being digitised includes a digital image (2-D photograph), species name, geo-referenced location, collector, collection date, the main purpose is to release data that had not been previously readily available.

The bulk of the digitisation process within museums is currently limited to 2-D digital photography, largely due to the cost, time factor and data storage. However digital imaging techniques are changing rapidly, as are the capacity for digital storage. The logistical benefits of creating a three-dimensional digital record of collections within museum institutions has been discussed above, however my practical research has been exploring the creative potential of photogrammetry. Through the creation of three-dimensional objects from two-dimensional photographs there are many options to use this information in many ways. My creative practice is exploring these options from generating physical object, digital animations and ultimately mixed realities (XR).
One of the creative explorations has been to develop a sculptural installation comprising three-dimensional prints based on photogrammetry models of natural world artefacts. It is influenced by the collection of Albertus Seba (1665-1735). Seba was a pharmacist and zoologist who accumulated one of the largest collections of natural curiosities in his time. These where called *WunderKammer* (Cabinets of Curiosities) and eventually when he passed away were sold off across Europe forming the basis for some of the most prestigious natural history museums in Europe (Musch, 2001). The three-dimensional prints act as a metaphor for the [4]Sixth Mass Extinction. Each of the prints will be coated in a matte black material that

[4] The sixth mass extinction refers to the next time that 75% of the planets Biodiversity becomes extinct, an increasing number of scientists believe that we are at the beginning of such an event.

absorbs 99% of the reflective light, so as to obscure their form, representing the loss of the original both from nature and as artifact. Representing another embodied experience that challenges our perception of the object is a series of digital photo animations. They will still reference the illustrated plates of Seba's collection (see *Figure 5*), loosely collated into taxonomic groups. This is a series of digital three-dimensional images will then serve as a marker as to how digital technologies are changing our relationship with the natural world.

Figure 5. Seba, A. 1735, Illustration from Seba's collection.

6. Conclusion

Technology has changed the ways in which we, the subject, can create, view and ultimately experience images, as these images become increasingly realistic this must ultimately change our perception of the image as object. As technology becomes more immersive then the boundaries between the natural and digital worlds will blur, thus challenging our relationship between subject and object. Through my research I have tried to explore just how we can adapt this change to our advantage. As we go from one climate crises to another it is becoming increasingly clear that our relationship with the natural world is fundamentally flawed, humans are having a detrimental affect on the environment that they require in order to survive. My research has looked at possible ways in which we can potentially alter our perception of the natural world through visual applications of digital

technologies; as it becomes increasingly problematic to experience the natural world, as our very presence causing more problems than solutions.
The natural sciences and institutions such as museums, particularly through western societies, are seen as being strongly connected to the traditional epistemological theories of Kant and Descartes (Grayling, 2019). However contemporary (continental) philosophies have largely disputed this point of view. This questioning of the traditional points of view, of Cartesian dualism, first appears in the theories of the Phenomenologists specifically in the ideas of Maurice Merleau-Ponty (1945). By placing the body (subject) into the experience of perceiving the object this creates what is known as an embodied experience, one narrows the subject-object divide. However this does not go far enough for the Object Oriented Ontologists, such as Harmann, they argue that this still creates an anthropocentric bias through which we perceive the world around us. As long as we view the world from an anthropocentric point of view we will always see the natural world as something "other", something separate from us.
Through the application of these theories into my practice led research my aim is to create non-empirical experiences that will explore new ways to understand our relationship with the natural world around us. As well as to investigate how technology and the digital image can immerse us, the subject, into a world that has up until now largely been viewed or experienced from behind glass. Another purpose of these installations is to question the impact that our anthropocentric bias has had on the natural world, the environment.
Also if it is possible that technology, through creative practice can raise awareness of our bias towards the understanding of our perception of the objects around us.

Towards Neurodesign. The Mental Effort in packaging design

Alessio Paoletti *[a], Lorenzo Imbesi[a], Angela Giambattista[a]

[a]Sapienza University of Rome, Department of Planning, Design, Technology
*alessio.paoletti@uniroma1.it

Abstract | User feedback collection methodologies nowadays also benefit from neuroscience tools and methods. Among the typical indicators of neuroscientific experimentation, there are three commonly accepted ones: Emotional Index, Interest, and Mental Effort. While the first two describe the affective sphere, the last notes the cognitive response. The tools needed for its measurement have become portable, lightweight, and readily available. This allows its use in real contexts, opening up to neuromarketing and neurodesign experiments. On the other hand, the method of interpreting the data is still underdeveloped. The contribution aims to increase knowledge of Mental Effort in the design community, summarize the tools needed for measurement by emphasizing the most accessible ones, apply an interpretation tool and present a possible one. Satisfactory results emerge from the case described, demonstrating that it is possible to use neurophysiological data to identify areas for improvement of the product.

KEYWORDS | NEURODESIGN, NEUROMARKETING, MENTAL EFFORT, USER-CENTERED DESIGN, PACKAGING DESIGN

1. Introduction

The importance of involving the user in the design phases is now well established, as emerged from the first researches of the 1980s and subsequent popular reference publications for user-centered design (Norman, 1988) (Nielsen, 2005). The user provides feedback that supports the designer in the creative process to meet real needs, with effective solutions, to generate successful products. Therefore, it has become crucial to be able to collect user feedback in an increasingly complete and reliable way. On the other hand, it is widely accepted that the human-stimulus interaction process is a holistic phenomenon that cannot be deconstructed into individual components without reducing the possibilities of representing it in its entirety. As Aristotle already stated in Metaphysics, the whole perishes upon division, and the whole is greater than the sum of its parts; assumptions that were then placed at the basis of various theories of perception, including the Gestalt. However, this fragmentation is necessary to analyze the process of human-stimulus interaction in a scientific manner and in its complexity. If we then consider a physical product rather than a virtual product, the complexity grows as the sensory channels involved increase: similarly, the complexity of the message received by the user increases. Just think of the tactile and olfactory stimulation alone to understand the complexity involved. In response to this complexity, scientific research is providing new tools and methods of investigation. A recent frontier is constituted by cognitive neuroscience, now able to outline the user's response through three neurophysiological indices. For a broader understanding of the three indices and their relationship with Design, please refer to a recent publication written by an interdisciplinary research group composed of researchers in neuroscience, psychology, design (Babiloni, Di Lucchio, Montanari, Paoletti, & Perrotta, 2021). Of these three indices, the Emotional Index and Interest measure the affective response, while the Mental Effort index detects the cognitive response. This contribution focuses on Mental Effort and its interpretation from a design point of view. For a case study on the interpretation of the Emotional Index, from a design point of view, see the research by Paoletti and Imbesi (Paoletti & Imbesi, 2021a).

2. Mental Effort and tools to measure it

The Mental Effort Index expresses the cognitive Effort the user applies when exposed to a stimulus. A user who wants to achieve a task through a product needs to understand how to use it to get the desired goal. The more Mental Effort users show, the less the product is easy to be used. In this perception, affordances play a crucial role: introduced in the scientific debate by Gibson (1979) and reworked in the concept of perceived affordances by Norman (1999) specifically for design. Further studies have then expanded the idea of Affordance, including Gielo-Perczak and Karwowski (2003). They have defined a framework to combine the concept of Affordance with those of emotion and intuition.

But how to measure Mental Effort? The latter is an index obtained from the synthesis of the user's brain activity measurements. Measurements can be made with different instruments, the main ones being functional magnetic resonance imaging (fMRI) and electroencephalogram (EEG). FMRI highlights neuronal activities by identifying the change in blood oxygenation and flows resulting from neural activity. In fact, the more active an area of the brain is, the more it uses oxygen. The necessary instrumentation consists of a tunnel in which the user is made to lie down. When the user I immobilized, the brain is scanned. This measurement then detects the regions of the brain that receive the most blood and therefore appear to be active. The limitations of this test are the cost of the machines, the resolution of the times, and the participants' inability to move. In fact, the participants are asked to lie down perfectly still inside the MRI machines during the recording of the images. Consequently, it is impossible to carry out measurements at the exact moment in which the user acts in the real context of use.

Unlike fMRI, electroencephalogram (EEG) can be performed using a portable helmet equipped with electrodes positioned in correspondence with the prefrontal cortex. Specifically for Mental Effort, these electrodes record the variations of the theta waves. The helmets needed for the EEG have, over time, become lighter, more portable, and more accessible. Indicative of the great attention that cognitive neuroscience is receiving from other fields of knowledge is the Open BCI project. Open BCI is an open-source brain-computer interface (BCI) project. From the hardware point of view, it is composed of open-source biosensors compatible with Arduino. It is designed to be low-cost for researchers, manufacturers, hobbyists and allows recording EMG, ECG, and EEG signals. The website (http://openbci.com/) provides the files needed so that the user can easily 3D-print the components at home. Likewise, the software necessary to obtain the data in a raw manner is also provided free of charge. Although the data is raw, it represents an excellent solution to allow most non-professional users to get closer to the EEG tool.

Furthermore, since communities are growing around similar projects, they lower the barriers related to specific knowledge. They provide alternatives to the expensive software needed to filter out the vast amount of data collected by the tools. The limits of the devices that measure EEG activity are the cost of the software, the specific knowledge required (which for a designer means seeking support) of a specialist in both neuroscience, software development, and statistics to reduce the amount of data to the significant ones.

The easy availability of the instruments, and the high portability of the devices that leaves the user free to act and move in a natural context, even from a laboratory, opens up new possibilities.

3. Mental Effort in Neuromarketing and Neurodesign

As seen in the previous paragraph, the tools for measurement have nowadays achieved a very high reduction in costs, dimensions, and weight. That allows measuring brain activity no

longer in the laboratory and assuming static positions, but in an authentic and daily scenario, leaving the user free to perform the desired action. These tools are mainly used in the field of neuromarketing, while in design, they are still a frontier. Neuromarketing applications range from the evaluation of preferences in the automotive area to preferences on the packaging by relating the smells and colors of the products. It's also applied to the assessment of the best combination between the message to be conveyed and the media to choose; case studies are growing and are covering more and more areas of communication and marketing (Monestina, Berdasco, Albiñana, & Royo, 2014; Vecchiato, Cherubino, et al., 2014; Vecchiato, Maglione, et al., 2014). As limiting as it is to define a rapidly expanding field of research, neuromarketing can be seen as: "the application of neuroscientific methods to analyze and understand human behavior in relation to markets and marketing exchanges." (Lee, Broderick, & Chamberlain, 2007, p. 200). It is easy to imagine how these applications can be translated to design if we apply these tools and methods to understanding user behavior while interacting with a service or product (physical or dematerialized). The recent research carried out has given rise to the so-called neurodesign:

> "Neuro design is the use of insights from neuroscience and psychology in creating more effective designs. What can psychology and neuroscience tell us about what is really driving where we look in-store and online, what we choose to click on or pick up, what makes us share an image on a social network, and what image cues help drive a purchase decision? "(Bridger, 2017, pp. 13-14)

While from the point of view of measurements there is a shared scientific basis, the data interpretation remains to the designer's experience. Neuroscience tools can indicate the user's neurophysiological response, but obviously, they cannot directly tell which characteristic of the stimulus-product has elicited that specific response. While the figure of the neuroscience specialist is fundamental in the measurement of the data, the designer's know-how is necessary for its interpretation. At the moment, however, little has been done in this area. Some steps have been taken towards the interpretation of the neurophysiological data from the designer's perspective, both in the creation of the theoretical bases (Paoletti, 2019) and in the construction of operational tools that the designer can use without a specific background in neuroscience (Paoletti & Imbesi, 2021b). Below is a case study of the interpretation of the Mental Effort for packaging design.

4. Interpret Mental Effort, from a design perspective

In order, therefore, to interpret the Mental Effort data from the designer's point of view, in his Ph.D. research Paoletti (Paoletti, 2019) hypothesized a correspondence between the neurophysiological indices, the processing levels of a product that emerged from Norman's research (2004), and the types of interaction defined by Desmet and Hekkert's studies (2007). Following the literature review concerning emotional design, Paoletti proposed the ME index as representative of the level of processing that Norman defined as reflective. This level refers to the users' conscious reaction, in which conscious cognition is involved in deep

and slow reflection. At this level, cognition provides an understanding of the external environment. The reflective level for Norman is the level of design that is based on the cognitive aspects. At this level, users reason about decisions, evaluate alternatives, and compare possible choices, using long-term memory and declarative memory. Norman defines the reflective level and develops it with the seven-stage model of action (Norman, 2013). In analyzing the product experience, in parallel with the ME, Paoletti identifies the ME as the most relevant during that phase of the product experience defined as an instrumental interaction. For instrumental interaction, we refer to Desmet and Hekkert's (2007) research, which describes the product experience as consisting of three types of interaction: instrumental interaction, non-instrumental interaction, non-physical interaction. During the instrumental interaction, the user evaluates how the use of the product must take place. There is a desired task that must be achieved, and there is a cognitive evaluation of how to use the product, which therefore assumes an instrumental role. This type of interaction is mainly based on the functional aspects of the product. Paoletti (2019), therefore, proposes some aspects of the product that the designer should consider when designing for instrumental interaction, which in the user's perspective are identified as the functional sphere. By defining these aspects relating to the functional sphere respectively F1, F2, F3, and F4, they can be used both in the design process that focuses on the functional area and in the inverse process of interpreting the user experience to assign the variations of the ME to the related product's aspects. To define the four aspects relevant to the functional sphere, Paoletti's research was based on the research conducted by Norman on the seven-stage-model-of-action. The four aspects pertinent to the functional sphere are F1 signifiers/affordances, F2 constraints, F3 mappings, F4 feedback.

When the product has correctly designed signifiers, affordances, constraints, mappings, and feedback, the conceptual model is straightforward. For example, the scissor object has two blades connected by a pin, which suggests their rotation; its handle has two holes that indicate where to insert your hand; furthermore, the smaller hole suggests inserting a finger, while the larger is clearly for the rest of the hand. In the example of the scissors, therefore, the signifiers, affordances, constraints, mappings, and feedback are appropriate and thus lead to a clear conceptual model: for this reason, we hypothesize a low ME; the instrumental interaction with the product occurs with a low cognitive load.

5. An example of ME interpretation for design

The principles of interpretation mentioned in the previous paragraph have been transformed into an operational tool in the form of cards, as better described in the publication of Paoletti and Imbesi (2021b). Below are the results of a measurement of the ME index and relative interpretation, applying this tool. The stimulus proposed to users was a packaging belonging to the category of the spout pouch widely spread in the food and beverage sector. The stimulus was selected in two variants, respectively stimulus A and stimulus B, of two different manufacturers but which apparently were very similar. The

stimuli have no significant differences in size, weight, material, geometry. The two apparently similar stimuli elicited similar ME values during the non-instrumental interaction phases but different ME values during the instrumental interactions, particularly during the unscrewing of the cap. The interpretation of the data was made following the card tool mentioned above (Paoletti & Imbesi, 2021b), and it emerged that the area responsible for this change was that spout's area. The data measurement took place during all phases of user-product interaction: initial stages of visual exploration, phases of product use, final steps.

During the initial, non-instrumental stages, in which users explore the product without any specific goal, the product communicates through its geometries. The signifiers are clear: the cap's gripping area is evident thanks to its position and size. The cap's knurling is a clear signifier that suggests where to grab; it also means to rotate to open the package by unscrewing the cap. So the use is explicit, the suggested affordances are clear, and there are no others to confuse the user; furthermore, the physical constraints reduce the possible activities to be performed exclusively to those necessary for the opening. For these reasons, the ME during the non-instrumental phases is similar for the two stimuli. We cannot say whether the ME values are appropriate or not, but they are similar. It would be necessary to build a case history to define a range of ME values acceptable during this specific interaction phase, particularly for this product. As mentioned, the interpretation is strictly case-specific.

Some differences instead emerge in the ME measured during the instrumental interaction. To open the product, users grab the packaging in the only rigid point under the cap and, with the other hand, unscrew it. Observing users while using stimulus A, we observed that this action was performed with a partial overlap of the fingers. While during the non-instrumental interaction, the physical constraints correctly suggested the only rigid point to grasp the packaging. During the instrumental interaction, this area was insufficiently dimensioned. Therefore, we have identified the characteristic of the product that elicits higher ME values in stimulus A than in stimulus B. This interpretation thus becomes the design direction to follow in the re-design of the product. It is evident that the product used as a stimulus has a low impact on the user's life. Applying these tools and methods can have a more significant effect if applied in contexts in which the quality of the user experience can have more significant consequences, such as in the medical field.

6. Conclusions

The crucial role of the user in the design process requires that measurable user-experience data be improved in quantity and quality. Today, cognitive neuroscience offers a new point of view from which to measure these interactions. Much remains to be done from a design point of view because simple measurement does not meet the designer's needs. It is necessary to be able to interpret the variation of the data in a design key. Some recent research has shown how to apply neuroscience to the world of manufacturing, creating

several neuromarketing case-studies. Other research has highlighted the possibilities that arise for neurodesign. Still, little research has provided tools and methods for interpretation. Based on these few and still partial research, we have framed one of the neurophysiological indices in the user experience. We have mentioned the tools necessary for measurement. We have highlighted the scientific contributions that can be adopted for interpretation. We have applied these tools to show an interpretation of the index called Mental Effort. This is only one of the three commonly accepted indices to describe the user's neurophysiological response.

Furthermore, since the perception's process is holistic, an approach that considers its parts separately is reductive. However, this is necessary for a scientific and at least initial study. Accepted this limitation, the results of a specific case study were described, in which the Mental Effort data on two similar products was interpreted. The illustrated case study showed how it is possible to identify areas for product improvement for a subsequent re-design. What could be obtained from neuro-tests is a description of a trend, not specific data. A subsequent one should follow each test to refine the result obtained in terms of the quality of the user experience. Finally, the case study shown is from the area of packaging for food and beverage, in which the quality of the user experience has mainly commercial consequences. But these consequences can be even more incisive if, for example, we consider applying these measurements and interpretations in other sectors such as biomedical.

“WIT” as a Sustainable Engine Overcoming Mind Fixation in Ideation.

Alon Weiss

Shamoon College of Engineering
alonwe@sce.ac.il

Abstract | Traditional design brief methods are not properly equipped to deal with the complexities of "the next industrial revolution" which demands smart solutions that will optimize human comfort. 'WIT' is a biomimetic design-thinking tool driven by the ideality design principles (IDP), developed to enhance product designers’ (PDs) idea creation abilities in the design process. The case study was conducted with a unique focus group: Jewish ultra-Orthodox product design students, who have an added layer of [external] blocks due to limited access to information and media that most other design students are exposed to. Applying the WIT tool assisted participants in coping with the design paradoxes, released mind fixation and, as a result, accelerated the creation of various creative and diverse concepts during the ideation stage.

KEYWORDS | DESIGN PARADOX, IDEATION, IDEALITY, WIT

1. Introduction

Nowadays, innovation is strongly connected to the design of smart products with reduced environmental impact, with the aim of moving toward a more sustainable society. Experts envisage that many domains will benefit from the progress made by this "IoT revolution," which will present an unprecedented demand for smarter solutions that will optimize human comfort. Consequently, there is a rush toward realizing and implementing new technological capabilities in smart solutions (Business Insider, 2016). At the same time, the competitive nature of the world of design, which dictates constantly changing rules and modifies the way humans live, has increased.

Ideation in the design process emerges from the 'WHAT' and the 'HOW' stages, and acts as a creative bridge where new ideas are formed (Johnson, 2005). The WHAT identifies potential attributes describing the functions of the solution space, while the HOW describes the method for implementation. Together, these form the design brief.

In the ideation stage, PDs may encounter several mind blocks on their path to developing an "ideal" design brief. For example, a common, known phenomenon is the 'design process paradox,' which is the natural cognitive tendency to comprehend the way things function by adjusting them to functional requirements as determined by the customer, redirecting these to the HOW (Ullman, 2010). Consequently, this limits the space between the WHAT and the HOW until it is almost non-existent. Given that every design decision affects and feeds the next action (Schön, 2017), this paradox can lead to additional mind fixation during the thinking process and, as a result, limit the outcomes of the ideation stage.

Resolving the paradoxes which exist within the design process is the essence of design (Dorst, 2006). In the case of the 'design process paradox', PDs must face their tendency to choose the safe option – that is, grabbing the first concept that occurs to them and executing it as a solution, and by doing so skipping the idea expansion stage (the WHAT) and rushing toward a specific design solution (the HOW).

We can look to Nature to help resolve the paradoxes which exist in the design ideation stage. Nature's principles have always served as a source of inspiration to the man-made world in the realm of problem-solving; its systems operate within restricted sets of conditions, minimizing waste and irreversible damage to the ecosystem and even enriching and sustaining it in an original way (Benyus, 1997). The "biomimetic" approach emulates nature's solutions, processes and strategy from a holistic, sustainable perspective. In design, this approach expands the range of possibilities through observing and searching for similar sustainable patterns of biological systems in nature (Helfman, Reich, & Greenberg, 2014).

IDP stems from the biomimetic approach and assists designers in their aspiration toward an "ideal" design. In ideality, which can be defined as a comparative model of the cost versus benefit ratio, the conception process can assist creators by maximizing positive effects and minimizing negative effects. Thus, the design solution can be executed in a more sustainable

manner (Tischner, 2001). An additional, equivalent sustainable strategy is to "get more with less," by achieving a greater number of benefits with fewer resources.

An ideal solution in today's world does not come solely from one designer's worldview (VanGundy, 1988); this may have been adequate in the past, but is no longer fit-for-purpose. In the IoT era, more sophisticated thinking methods are required; tools that deal with the relationship between the WHAT and the HOW, and focus on the IDP in order to solve new challenges and to encourage creativity that will lead to an ideal design approach (Ackoff, 1978).

2. 'WIT' METHOD

WIT is a bio-inspired design thinking tool, a new WHAT method which incorporates an additional, IDP stage. This structure is designed to shift PDs' mindsets during ideation, and as part of a systemic, logical framework, with the aim of encouraging inventive thinking and the formulation of ideal product design briefs.

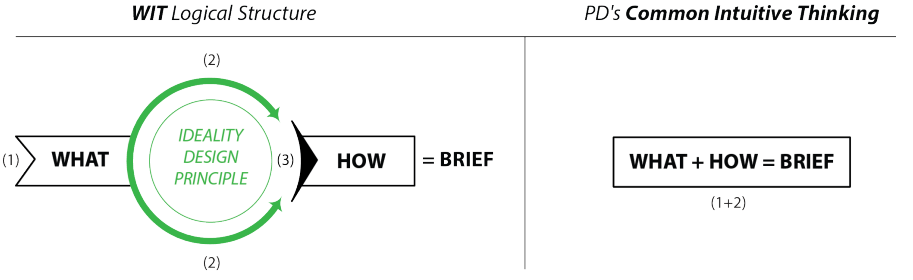

Figure 1. The WIT method's logical structure

Just as nature solves its problems in an ideal approach (Volstad & Boks, 2008), so too does WIT guide the PD's thought process through a series of logical, directed questions with the aim of increasing the level of ideality in the outcomes: increasing the system's advantages with practical functionalities, while minimizing the costs and harmful functions of the system by implementing unique design strategies and principles (A. Weiss et al., 2016).

Table 1. IDP questions employed in the WIT method

Reducing Costs (Resources)	**Increasing Benefits (Optimization)**
1. Defense Strategy – aim: prevent disturbances, malfunctions and system damages. Will be carried out by implementing the design principle of: 1.1 reducing surface area, friction, load, turbulences, etc.	1. Multifunctional Planning Strategy – aim: saving resources. Will be carried out by implementing the design principle of: 1.1. Expanding the functions associated with one structure in the product
2. Opportunistic Strategy – aim: preventing waste of existing resources.	2. Amplifying Strategy – aim: increasing product effectiveness and impact.

Will be carried out by implementing the following design principles: 2.1. Matching structure to function	Will be carried out by implementing the design principle of: 2.1. Creating an amplified effect of the system's components (accentuation, duplication, expansion, collection, etc.), and increasing interaction and synergy with the environment
2.2. Symbiosis – reciprocal interaction between product and environment	
2.3. Utilizing environmental resources	
3. Effective Resource Management Strategy – aim: preventing waste of existing resources. Will be carried out by implementing the following design principles: 3.1. Synchronizing system components	
3.2. Improving and saving energy conductivity, preventing energy waste	
3.3. Relinquishing redundant parts	

The main objective of WIT is to assist PDs in overcoming cognitive obstacles by focusing on the WHAT, while avoiding the tendency to quickly jump to the HOW. The essence of WIT is to enable PDs to think beyond their preliminary solutions by creating methodical, cyclic thinking which breaks free from common linear thinking; to stimulate a broader approach within biomimetics' existing constraints. Applying the tool eliminates PDs' habitual mindset barriers, thus serving as a design platform for the creation of a schematic but creative thought process.

3. CASE STUDY

This case study aimed to examine the effectiveness of WIT with the specific target audience (described below in Section 3.1), analyzing the participants' performance before and after applying the WIT and testing the study hypothesis (see Table 1).

Information was collected using both online and offline methods in order to achieve an extensive range of results, which were examined using an integrated research approach. In this way, the author sought to examine the WIT process as a researcher firsthand and subjectively, through small focus groups divided into control and test groups, in order to evaluate the participants' outcomes. The approach allowed the author to receive an objective and broad view, in a statistical manner, on the tool efficiency.

Gathering of information helped identify the various cognitive phenomena users experience when applying the method, and how this influences their results. The information collection process used a purposive sampling method and the data collection was done during the participants' trial with the WIT.

Table 1. Case Study

Research Question	Does WIT assist in eliminating PD students' fixated thinking patterns during the ideation stage?
Hypothesis	Using the WIT releases fixed design ideas during the ideation stage.
Criteria	Self-growth mindset Creativity Concept diversity / quantity
Research Methods	Integrated quantitative and qualitative methods

3.1 Unique Target Audience

The participants were students of the Mercaz Charedi Institute of Technology in Israel's undergraduate design program. These participants can be described as a complex target audience. Members of the ultra-Orthodox Jewish community in general, and their academic world in particular, are characterized as being closed, going to every length to maintain their strict principles in every aspect of their daily lives. This method of education limits students' access to information, and even censors the little content to which they are exposed, by preventing members from accessing mass media, general information and even blocking the Internet. Thus, this focus group is both unique and extreme as compared with students studying in parallel secular academic programs, who are habitually exposed to media content, which greatly influences their ideation performance.

This case study, therefore, tests whether WIT is effective even when employed by a group with a unique ethnic, personal, and cultural background. More specifically: will students with no practical experience, specifically students without access to influential content, be limited in terms of their ability to implement IDP? Or does the WIT require adjusting based on users' lifestyles and backgrounds? If the experiment is a success, will it be possible to substantiate that the methodologies were verified under extreme experimental conditions?

4. Methodology

The experiment was executed on Google Docs and lasted a total of 120 minutes, with 12 third-year students in working groups of 2-3 participants tackling a single design challenge. Participants' process and outputs in solving this challenge were examined in two stages, pre-exposure (Task A) and post-exposure to the WIT (Task B). The effectiveness of the WIT was measured according to three criteria: self-growth mindset, creativity, and concept diversity/quantity (see Table 1). Proposing concepts was optional, while the last part of the study was a mandatory quantitative questionnaire that also included the participants' feedback on the WIT tool.

Table 2. Research tasks

Task A	Design concepts should be formulated using intuitive ideation approach, demonstrating the diverse range of methods the participants have been exposed to thus far. Participants had to fill in at least one option; proposing additional concepts was optional.
Task B	The WIT was thoroughly explained using a chart. Participants were then asked to explore WIT's "Reducing Costs" and "Increasing Benefits" strategies (as described earlier in Table 1), through the creation of a design concept that would match each separate strategy, according to the following algorithm: "Description of the strategy – aim: Describe the principle's characteristics. Will be executed by the design principle" (A. Weiss, 2015).

4.1 Test Case Description

In both tasks A and B, participants were asked to propose concepts aimed at offering simple, manageable maintenance solutions for homegrown vegetables and herbs.

Background: "Urban family life today is characterized by living in apartments with no green space. Furthermore, the global decrease in meat resources affects the rise in demand for homegrown vegetables for private family consumption. Also noticeable is the ever-growing trend of health, diet and nutrition awareness, which promotes increasing the consumption of fresh vegetables and herbs."

5. Results

Task A lasted 30 minutes. Each team described a maximum of two ideas, providing mostly standard solutions, and some creative interpretations. The participants focused, for the most part, on the functionality of the planter, how they would implement the solution in their workshop, and which materials they would use. Most teams had one or two ideas to present, while a small portion of the teams presented a third idea.

Table 3. Task A: 9 of 13 total concepts presented pre-exposure to WIT

1	Miniature glass greenhouses, to be placed on balconies or in windows, using an artificial light source integrated into the enclosed housing. The system can be hung or placed on walls to minimize space consumption.
2	Vertical gardening device attached to windows.
3	Herb rack sprayed with soda water to repel bugs and an automatic watering system attached to the window.
4	Device hung from the ceiling, which opens up when pressed. Minimizes space consumption.
5	Portable adjustable device that folds up.
6	Kitchen counter planter, placed at a short distance from the faucet in order to reuse water for watering purposes. Connected with a spout at the back of the sink.

7	A smart pot with an automatic water and natural light control, measuring and supplying the amount needed through sensors.
8	A planter located near an organic waste bin.
9	A kit with a special cutter and cleanser of herbs; once the herbs are grown, they are properly cut, and if needed the plant is removed and the soil cleansed.

Task B lasted 90 minutes, during which the participants described approximately one idea for each strategy, producing an average of 4-5 ideas beyond the two ideas that were initially suggested. Most of the ideas written during Task B related to the general concepts described in Task A.

Table 4. Task B: examples of concepts post-exposure to WIT

Increase Benefits	
Multifunctional Planning Strategy	
1	Growth of vegetation on graded levels to reuse water and save space.
2	A pot structure that allows collection of water drops from the air and waters itself.
3	The plant produces pure oxygen, such that a device can be constructed to collect it for human use.
4	A terrarium for fish and plants with vents to allow the entrance of oxygen, and a net that filters air and water, and prevents entry of pests.
5	Vents covered with a net, which only allows oxygen to filter out.
6	A planter located near a water source, with a mechanism that collects grey water and filters it for reuse.
7	Some of the levels can be dedicated to composting by adding a suitable lid.
8	A smart pot structure with air channels for enriching oxygen in the plant's roots.
Amplifying Strategy	
1	Sensors that check and send an update about the vegetables' ripeness.
2	A pot that is able to collect the seeds of fallen fruits and replant them, creating a new plant.
3	A soil maintenance system that allows the soil to remain loose, even after several irrigations. The loose soil could be moved to a different soil receptacle, which allows the roots to continue growing, giving the plant more space to grow.
4	Additional educational information on calories, vitamins, recipes, and a connection to the community to enable sharing and exchange of information.
5	Incorporating fish into the terrarium, thus the water of the fish helps the vegetation grow and also improves visual appearance and ambience.
6	A wall of plants located in the sunniest spot, with a solar system that uses the sun's rays to activate the filtering and watering system.
7	A mechanism that allows the plant to receive its optimal water supply, thus monitoring its growth.
8	A water-filtering mechanism that also acts as a regulator of the water supply.
9	A smart pot with a light control that controls light waves and optimizes the plant's needs.
Reduce Costs	
Defense Strategy	
1	A flexible material structure that adjusts itself to various spaces, and can be easily cleaned and folded for minimal space consumption.

2	Protecting the growth zone by creating a border to avoid contact with pests or children.
3	A designed planter structure that allows the usage of sustainable energy sources, such as watering and fertilization, by locating the planter near a grey water source and a composter.
4	Dripping fluids that emit an odor to repel pests.
5	A smart system that prevents unwanted pests from harming the plant.
6	A smart pot surface that rejects dust.

Opportunistic Strategy	
1	A device placed on air conditioning units to reuse the air conditioner's water for watering purposes.
2	A pot that collects water from the air to accumulate water drops and waters itself (e.g. in nature, the Namibian desert fogstand beetle is able to perform this function).
3	A smart pot with a form and shape that transforms in accordance with weather changes, reflecting environmental symbiosis.
4	Placing the planter near an energy source; for example, as part of the trash bin or hung on the bin, in order to expose the plant to organic fertilization sources.
5	A product that functions using a solar system.
6	A watering tube that is connected to the home water system for optimal use.
7	Filling the terrarium with water by extending the air condition tube into the terrarium, such that filling water is not done manually.
8	Placing the plant directly under the sink, thus allowing maximal use of running water, with a control unit that measures water usage.

Effective Resource Management Strategy	
1	The pot's system informs when vegetables or fruit are ripe for eating and should be picked, or if it's time to trim the herbs.
2	A pot with several compartments for growing different types of plants in one pot, with a control unit that can supply each plant with its appropriate water needs.
3	A plant system that allows the plant to draw water according to its needs. A single water supply can be connected to several plants, as water passes through each one and stops when the plant reaches its ideal moisture point.
4	Filtering system that reuses shower water and expels its chemical soap components.
5	A planter design with a monitoring mechanism that checks the plant's condition in terms of water supply and fertilization, and also announces the ripeness state of the plant.
6	A tube connecting the faucet to the planter or pot, based on the communicating vessels rule, to allow water movement and regulation.
7	A smart pot with a mechanism that can synchronize and control the plant's growth, such as irrigation, fertilization, light control, etc.

5. Discussion

The participants were presented with the research stages, with Task B requiring additional time for explanations on the researcher's part.

In Task A, pre-exposure to the WIT, participants easily launched the first idea, but then quickly fell into a state of fixation and struggled to think of additional ideas. The traditional method provided capabilities of quick, intuitive thinking and creative ideas, yet, at the same

time, also limited the search within the participants' knowledge space. Post-exposure to WIT, participants were able to reach new search spaces by exploring the useful features of the planter, as well as via usage environment: it was evident that this new approach strengthened the group's cognitive abilities and broke barriers.

Table 5. Quantitative research findings

Design Stage	**Task A: Pre-Exposure**	**Task B: Post-Exposure**				
Method	Various traditional methods (Jones, 1970)	WIT				
Design Strategy		Increase Benefits		Reduce Costs		
		Multifunctional design strategy	Amplifying design strategy	Defensive design strategy	Opportunistic design strategy	Effective resource management design strategy
Cases of Concept Expansion	13	9	8	6	8	7
Total	13	38				

Participants collaborated well during team brainstorming and made use of quick sketches of ideas that facilitated communication between team members, helped strengthen their thought processes and develop additional ideas. Additionally, there were instances in which ideas were adapted for multiple strategies and resulted in an in-depth discussion. These ideas could be divided into sub-ideas and assigned to more appropriate strategies. All these created a flow of new connections that led to new ideas, in addition to the high level of creativity due to the elimination of limitations.

The participants' resulting ideas were vast in quantity and highly diverse, with a ratio of 3:1 in favor of the WIT method. In total, an average of 7 ideas were suggested. On average, pre-exposure to WIT, participants were able to produce 1-2 concepts. Post-exposure to WIT, however, participants were able to produce approximately 6-9 concepts, which is a significant increase of approximately 200% in the number of ideas generated. The ideas in Task B required more time; however, they reinforced the thought process beyond the standard processes demonstrated by the students in Task A of the experiment.

Participants presented high quality thinking abilities both pre- and post- exposure to WIT. However, it was only following their exposure to the WIT that the participants' thinking processes were forced to remain in the domains of the new strategies, and their performance showed significant improvement. These improvements were mostly apparent in the fields of thinking flexibility, creativity and innovation. Specifically, the ideality concept forced participants to think beyond normative patterns and remain in each strategy domain

longer than is typical in the intuitive thinking process, resulting in a greater number of concepts.

Likewise, nature's restrictions fall under the principle that "necessity is the mother of invention." Restrictions and limitations within various living conditions are the engines of innovation in nature. Biomimetic solutions within nature's systems are often found in the most challenging environments and extreme conditions, and yet, the resulting solutions improve survival conditions and continued existence. For example, in nature, seed distribution mechanisms of plants implement a wide and creative range of solutions in order to ensure the continuation of the next generation (Barker, 2009). The challenge is finding a way to disperse them without innate movement capabilities. In design, limitations, such as extreme conditions, limited access to information, or conceptual impediments in a trained thinking process, all serve as an engine that can propel students, by way of nature's IDP, beyond the normative limitations of the thinking process, becoming fertile soil for idea expansion. In turn, exposure to several unique concepts allows us to perform a more precise decision-making, by choosing one or combining several, bringing PDs closer to an ideal concept worth further development and investigation in the solution space (Ullman, 2010).

In addition to examining the effectiveness of WIT, the majority of participants (74.2%) voted positively in their questionnaire, which illustrates that use of the WIT aided in examining new and unusual spaces, and overcoming obstacles such as existing mind fixations, at the ideation stage.

The results of this case study show that WIT is suitable for students of a unique ethnic, personal, and cultural background. These results prove promising in substantiating the effectiveness of the WIT method (as the WIT was already shown to be effective with another, more mainstream test group (A. Weiss et al., 2016)), especially since it was unclear whether BA students in general, and students with limited interaction with outside media in particular, would be able to implement ideality design strategies. It is worth continuing to study this question with PD students of different backgrounds to continue optimize WIT's overall effectiveness.

The research analysis emphasizes WIT's ability to aid in shifting from common, traditional and linear thinking patterns, often affected by mind fixations, toward fresh, new thinking patterns. This contribution is mainly evident in the enhancement of students' growth mindset, which occurs in three phases, as well as in the quality of the resulting outcomes. The first phase of the method forms an analytical linear thinking pattern and expands the search time. The second produces a systematic thinking pattern via analogical creative thinking. In the third phase, an intellectual awakening is evident, leading to a focused and intuitive thinking state, thus enriching the synthesis process of the design.

6. CONCLUSION

Applying the WIT within the ideation stage can act as a catalyst for thought, accelerating the flow of creativity, thereby shifting the designer toward newer realms of possibilities.

The tool is effective for PD students, particularly those of a multicultural ethnic group with a unique personal and cultural background. The difference in the achievements post-exposure to the WIT was significant. The students' thought processes were more open, more ready to cope with cognitively challenging mindset modifications, and able to break from a trained mindset acquired during their studies. In this unique focus group, the WIT design process stimulated the participants' creative brainstorming capabilities in the teamwork process, acting as an engine for expanding their thinking and allowing them to dive deep to cope with their own conceptual limitations – as was reflected in the increased quantity of diverse concepts. Necessity is the mother of invention, and the WIT's embedded restrictions and limitations on the different mindset conditions can serve as engines of innovative thinking – assisting in releasing mind fixations in the ideation stage.

The fundamental difference between traditional methods and WIT lies in its perception of time. Whereas traditional approaches examine the design challenge via facts and findings that exist only in current systems, WIT's ideality-based approach widens the realm of possibilities by focusing on finding solutions by looking at possibilities that may exist in futuristic systems. Thus, WIT leads the mind toward an optimistic mindset that reinforces positive functions, and aids in exposing deeper layers of the problem space objectives, resulting in the creation of innovative ideas.

A designed generation: Maker's maturity and social responsibility

Luca D'Elia

Sapienza University of Rome
luca.delia@uniroma1.it

Abstract | The following paper is a first step towards a research path that investigates the role of the craftsman and new craftsmanship in the machine society. The research looks at the post-industrial panorama, the actors on stage and the effects that this revolution has brought, is bringing and can bring to the artisan activity. A context with a strong identity and a culture of know-how that has allowed, together with technological progress, the emergence of figures such as the Maker, the digital craftsman. A figure that is only recently beginning to proclaim itself as such, but still floating in a limbo of identity ambiguity. As uncertain instrument of this new 'productive group', also the technological potential risks failing its role. Craftsmanship and post-craftsmanship perhaps have the opportunity to cooperate in order to achieve a result greater than the sum of the parts.

KEYWORDS | IDENTITY, CRAFTMANSHIP, POST-INDUSTRY, AWARENESS, ECONOMY

1. Introduction

"The territorial and production context is defined by the set of skills and experiences settled over time, productive knowledge consolidated at individual, family and group level and, moreover, by the bonds, which are also consolidated between companies and people."
(Tosi, 2010)

Modern production systems find their foundation in the artisan realities and in the culture of know-how typical of a tradition that is slowly disappearing. A production that, in addition to be a pride in the world, is a central sector of an economy that reflects the mechanisms of society (Follesa, 2017). The building blocks of the development process of the global society, the liberalization of markets, have intervened as devastating factors in small-medium enterprises. Today, as reported by the latest ISTAT trade analyzes, in Italy in 2018 there are a total of 1.7 million of craft activities, reporting a decrease of 3% in the last 3 years.
Faced with a crisis in the planet's resources, the current consumption and production model leads us to redefine and question many practices that have been implemented so far. There are numerous critics and scholars of the current economic system who propose 'lateral' alternatives to development, through the application of concepts such as the necessary degrowth of Serge Latouche (2007) in "La scommessa della decrescita", or the "Crescita felice" by Francesco Morace (2015). The quantitative approach, according to these studies, must move towards a qualitative approach.

2. Crisis design: facing productivity crisis we produce new production tools

European policies announce for 2020 guidelines based on smart, inclusive, sustainable growth by promoting and developing an economy based on knowledge and innovation, more aware and rigorous in terms of resources. An attitude that at the same time favors both social and territorial cohesion through new indicators of well-being which, according to the "Report by the Commission on the Measurement of Economic Performance and Social Progress" by Joseph Stiglitz (2009), seek to outline aspects beyond of merely economic/monetary values, trying to conceive of well-being as the union and balance of social, environmental and economic capital.
From the material consumption point of view, the European Commission is working to standardize the calculation methods for the main environmental certifications in order to make the consumer more aware and responsible in the purchasing phase. High types of traced and tracer labels attempt to integrate social aspects through recognition of human rights and mapping of the entire production chain, including workers. There are collective scenarios such as those put in place by the Commons Collaborativo (Rifkin, 2014) that are becoming increasingly current and feasible. These aspects, through the concept of interdependence in the network, define new consumption models that go beyond mere possession in favor of exchange and services.

2.1 An unpredictable design: distributed productions generate values that the market cannot control without indulging them

The most recent social and economic transformations have shown, both in the context of global development and in the national economy, a crisis of production balances and questioned the development models that have defined and guided local production in the last forty years, reducing progressively the degree of competitiveness of craft businesses. This loss is exacerbated by the constant contamination of culture carried out by globalization and by the massive industry which tends to amalgamate cultures to expand its catchment area. Lyotard defines the end of the great narratives in "The post-modern condition" (1979) as a loss of identity dictated by a single cultural strand composed of the sharing of certain values. The homologation of these paradigms, which aim at a more economic than ethical model, determines the end of this meta-narration of which the philosopher speaks and marks the departure from traditions and cultural values generating radical movements and works of 'rupture'.
The growing amount of innovation that is emerging thanks to radical and widespread movements such as Open Source, which from the first experiments such as the human genome project (HGP) has evolved to the present day, distinguishing itself as a real means of innovation on a global scale (making the term 'open innovation' coined in just 10 years), favored the advent of new thought tools such as the J.S. Brown's *Thinkering*, a portmanteau of 'thinking' and 'tinkering' (Antonelli, 2011). Regarding this revolution, Andrea Branzi (2017) states that the widespread and distributed nature of modern design (referring to design as much as to architecture) makes it difficult to identify a single will, defining it as a militant and fluid link.

"…just think that during the Salone del Mobile there are more than 400 exhibitions at the same time, all projects not intended for the market, but an expression of an idea of reform of the environment, the city, the habitat, to realize that it is a widespread avant-garde form. Less evident, perhaps, but with an anarchist, reformist base and with a surely greater number of employees than we had." (Branzi, 2017)

The result is a series of small unpredictable innovations, as Pasquale Gagliardi (2017) defines them, which clashes with a practical market that tends to favor a *'planned change'*.
Innovations that fall within a programmed scheme or that are easily recognizable within an economy that, although dynamic, must remain predictable (A scenario extremely dissimilar from that structured by the Schumpeterian theories on which many companies base their business model). The issues related to the relationship with local resources and territorial identity are the basis of projects, studies and actions in different sectors of industrial design and especially in the field of design applied to corporate territorial systems.
In Europe, specific directives on development activities push nations and companies to feed internal production in order to support their own development if they do not want to see their production system reduced to what Bauman calls an economy of only transit and exchange of goods and people.

2.2 A design of necessity: digital manufacturing as creative process design tool

In response to these needs there is a fervent return to the local, a new economy from below, sustainable and respectful of the diversity of the territories that could truly outline a strategic vision of the productive future. Just think of the role of the makers and the rapid social responsiveness of rapid manufacturing which has led to the proliferation of communities and places such as Fablab and Co-hub, where the interdisciplinary exchange of skills is in favor of the development of innovative start-ups and cultural growth of the cities in which they operate. The technological update of Industry 4.0 and the adoption of certain production technologies (such as FDM or SLA / DLP) run in aid of an increasingly demanding market attentive to the central role of the final consumer. This rapid expansion has moved the planned obsolescence market above all, which has obviously felt called into question in the face of an instrument that can reset its competitiveness. An interesting program launched by Groupe SEB (which includes industry giants such as Moulinex, Tefal, Rowenta), is the "10-year reparability commitment", a mapping of 'repairers' that offers the possibility of finding 3D printed parts to replace of the components that can break over time in the products. Jan Middendorp of LettError describes the importance of tools for a designer, referring however to artisans as their ancestors. The latter, according to Middendorp, were like disgruntled customers in the 'tools' market and for this reason they have always tried to make their own, to personalize their work environment.

"*They always had the tendency to personalize their tools, to appropriate them by honing them, converting them or expanding them. The more specialized the work, the greater the demand for customized or individually made instruments."* (Middendorp, 2000)

The opportunity offered by some experimental and consolidated technologies, gained thanks also to the Open Source communities and the digital manufacturing machinery industry, to be able to apply these tools and innovations to any production sector and, as well as design has become more evident participated and a fundamental part of the most disparate disciplines, so the role of the designer is redefined under an ethical key for which the design process itself is the fulcrum of the activity and acts as a coordinating element capable of managing the various skills at stake and work and production flows.

"*It is not just about 3D printing technology adoption. Inserting a 3D printing sub-process into traditional stamping will likely require process redesign*" (Brody, EY 2016)

Danish designer Olivier van Herpt launched in 2014 Adaptive Manufacturing, a collaborative project with the help of Sander Wassink. The project starts from the assumption that technological production has replaced the craftsman and therefore removed all traces of human and local influence and how this 'ambiguous' digital manufacturing process can mediate the language between the two realities.

"*At the foundation of every product there is the production process. When we replaced the craftsmen by machines, we lost the translation of local influences into our products. What if*

our machines could become more sensory? What if the machine could sense the local environment and incorporate it into the production process?" (Van Herpt, 2014)

The research of the two designers examines the ways in which it becomes possible to regain that lost connection between the production of objects and the objects themselves. To do this, they decided to design scripts that distil shapes and textures from external phenomena. External information, measured by sensors, is then translated into specific printer behaviors via software. A sensory and sensitive machine that perceives the environment and therefore binds to a specific territorial context, translating the input into a specific movement, position or raw material. Here the designer still plays a fundamental role by defining the degree of sensitivity of the machine and the elements to be considered. These approaches and experiments let think about the role of the digital manufacturer. In addition to demonstrating a willingness to declare themselves through their products, making them unequivocally attributable to their work, they show an exquisitely melancholy taste in their past, artisanal, traditional and local realities. Through the readjustment of past products or the use of traditional materials, the need to combine digital manufacturing with a world in decline seems to emerge until questioning if it is out of a real nostalgia or a secret will to confront the massive industry.

3. The responsibility of design: the centrality of design process given by its complexity

Regarding this, Enzo Mari (2006) speaks of an almost criminal role of design in its being an instrument of proliferation of new goods in a world already submerged by them. In fact, Mari condemns the creative process and the search for innovation by attaching an almost criminal role to the current landscape which is dominated by unnecessary overproduction and a senseless frenzy. These words recognize the traits described by Gagliardi of a revolution that is not guided by a thought or a will capable of evaluating the social impacts that such innovations can have. We live in a period full of 'tools', but with ambiguous ends. According to Mari, the designer must look at human needs outside the market conditions when developing a project. With a severe denunciation of the progressive deterioration of today's design work, the main culprit for this situation is the global market that requires an object to be producible and salable in every part of the world. The role of the designer is thus diminished to a simple 'signature' to be affixed to series of objects in which any construction philosophy is lacking.
The designer should be in a position to respond to this 'ambiguity' by providing a complete and reproducible analysis tool that is able to put a more willing and interested market at the service of technological innovation, aware of its development and potential. A working method that would be able to create products from a synergistic process between technological research and the morphological and social spheres. Enzo Frateili (1969) defines design as the result of the combination of three factors: language, function and meaning as indeed they refer to three specific study areas, morphological, technological and social respectively.
In this sense, the role of the designer acts as director of these categories to favor their synergistic development and offer a result greater than the sum of the parts. However, the

designer is not at the center of the action, but he becomes a multifaceted and dynamic figure that insinuates himself into the individual disciplines and regulates their input and output.

3.1 A complex design: technological development confronts industry with radical changes in production dogmas

A system like that one just introduced perfectly coincides with the description provided by Alberto Gandolfi (1999) of a complex system, which combines the advent of digital, electronic computing, at the moment of true understanding of what really is a complex system and the realization of how this complexity is inherent in everything that surrounds us, from the physical and biological nature of things to the texture of the social fabric, from production systems to political systems. These systems are in fact represented as hierarchical constructs where each level of this scale is regulated by a network of interdependence and continuous circulation of data (input and output) which, thanks to the complexity of the system and of the individual parts that compose it, in order to generate outputs of greater importance than the sum of the inputs.
If, by its definition, design is a process, as such it does not have a single interpretation and result but is a useful tool for understanding a whole series of social, productive and fruitful processes. An interdisciplinary discipline that has now imposed itself in almost all sectors of research and development, as well as production.

"We are not experts in a specific subject ... we are experts in the process that leads a specific subject in bringing innovation" (Kelly, 1999)

Design as discipline has evolved in step with the technologies that have allowed this material to express itself in new forms and, precisely because it is driven by this impetuosity, it has evolved and complex over time to take on so many facets to become an extremely difficult subject to understand. Taking up the words of Bruce M. Tharp, and the study that led him to define the 4 major themes of contemporary design scenario: *"Design is pretty much a mess"* (Tharp, 2009).
Without a convincing, truly taxonomic way of organizing the design activity, the latter risks leading to misunderstood results; the risk, for the designer, becomes that of being scattered and vague.

3.2 Designing awareness and behavior in front of the innovations

It becomes imperative to endorse critical thinking towards a system that develops responsible and empowering policies. In this way of thinking we look at the Responsible Design, which has a relationship with the market, defining itself 'commercially available' and whose primary intent is not a profit maximization but rather to serve the less wealthy (E.g., a public tap that closes itself after a certain period of time). On the other it is possible to talk about an Empowering Design, which has little to do with the market but is closer to a critical intervention towards an attitude to be rectified (E.g., a tap that shows you how much water you are using and gives the user the environmental impact awareness).
In the world of 3D printing, it is not difficult to associate the role of plastics, and it has been,

fortunately, equally easy to find alternative and ecological solutions to the question. Today, various materials are developed directly deriving from industrial plastics that would otherwise risk ending up at the expense of governments or the environment itself. Instead, what is most difficult to see is what has been carried out in productive consumption and waste management. For instance, the waste generated around the food sector and how digital manufacturing has offered an answer. We could be able to produce pseudo meats and edible compounds from food waste, and there is nothing that excludes that one day it will reach our meal consumption. Nonetheless, as per Scionti experiment in 2018, a 3D printed steak, will have to look as a regular steak in order to be recognized as it is. Robert Artigiani (1987) stated that even in front of radical changes, characteristic elements of the previous system must be maintained, in order to achieve a minimum perceptual and existential stability. Just as in 3D printing filament production, we have increasingly sustainable materials (in economic and ecological terms), derived from the recycling of the same bio-plastics, technologically performing and aesthetically appealing but which are produced in a less ecological way (given the limited accessibility of industrial complexes to renewable energies), in an increasingly aggressive and competitive market context and distributed in ABS containers and spools and sealed in common plastics.

4. Towards new products conception

The economic and social crisis, mentioned above, focuses on the need to identify new development models that take into account the deep interdependence now active between the different economies and the potential expressed by the development of communication and data exchange systems. According to the study by Warnier (2014) the development of new small-scale production techniques will allow the transfer of power from the hands of industries and those who regulate the infrastructure to those of the designer and consumer, who today more than ever is identifying himself as the only figure. In fact, Morace redefines the role of the consumer, referring mainly to the Italian context, which is becoming more aware of the production and creative processes and increasingly interested to them so much that he wants to be an integral part of them. From *prosumer* to C*onsumAuthor*, a hybrid figure who directly participates in defining and selecting the prototyping lines of products and services, assuming their identity and involvement (2016).
A concept that is closer to the world of luxury and an almost elitist market, but which in an increasingly social and open context is actually spreading like wildfire on almost all market levels. Since the days of Apple, the concept of branding had been introduced, or no more than just brands. A fluid, inclusive system, in constant transformation and improvement where the consumer, the community, feedback play a fundamental role in the development of the activities themselves.

4.1 A physical design: product circulates on digital platforms, but acquires its value when we can touch it

Therefore, the Research investigates the responsibilities that design has developed with regard to everyday products and in particular with the products to which the new generations especially refer, to which the cultural and social values of the context of belonging should be handed down, who today more than ever are able to define, recreate, hack, reprogram this

context. A first question that arises is how is evolving the concept of product by including those that are being created nowadays. To answer this question, perhaps the question can be circumvented not by looking at the present *ConsumAuthor*, but at those who will come.
The well-known digital divide created with the new generations has become consolidated and we increasingly have free access and understanding of digital systems. Nonetheless, the physical interaction and therefore the contact with matter remains, such as the need for the mind to establish a relationship, an experience that is not only visual or auditory, but above all tactile. Mulgan (2017) clarifies how the artifact, the physical object, in each of its declinations, facilitates large-scale coordination (referring to the interaction created in large connective intelligence systems and collaborative societies). We are used to thinking with things and we struggle to do it in their absence. Large-scale cooperation and coordination generate a schematization and vice versa.

4.2 Digital manufacturers identity: the result of a new product and production conception

At the basis of the reflections set out so far, the research deals with the relationship between design and production and the different ways in which the design discipline must be placed towards a post-industrial production, paying particular attention to the identity, defined by the tools themselves, rather than by geopolitical or cultural characters. It must investigate the identity of objects and the different ways in which this is built in relation with the social context and from there with both material and immaterial resources.
At the basis of this reasoning there is the assumption that there has always been a correspondence between objects and places and that such correspondence has been interrupted (or at least weakened) with the advent of the machine society, the expansion of an economic system always more open and inclusive, and with the substitution of codified knowledge for practical knowledge.

5. Discussion: what future of Maker holds?

In this socio-economic evolution, design plays a primary role.
On one hand because of its being an important discipline in the development of production systems, and therefore central in defining new possible alternative economic scenarios, and its ability over time to have become so multifaceted and interdisciplinary as to play a role in every production system. On the other hand, for the responsibility that is unanimously attributed to it in the development of those consumer dynamics that have accompanied the progress of globalization.
Having outlined the panorama, the context, and the direction that the research wants to take, it becomes necessary to filter from the pool of potential results and sectors to which this research can be applied. We are most likely in the middle of what Gandolfi (1999) calls a 'catastrophic bifurcation'. Micro-oscillations of confusing revolutions (entropy) are about to transport us into a future in which each individual will have full responsibility (enthalpy) for its own work and creation. It can no longer be said that we are at the gates of a revolution and the risk becomes that of letting it get out of hand or worse of using these tools unconsciously. The question emerged at this point becomes: does the designer who 3D

prints, really develop his design by virtue of 3D printing or exploit manufacturing as a tool for creating a design?
We usually think of production systems with two distinct figures: designer and developer, architect and worker, mind and arm. This gap is about to disappear. If we have now witnessed a series of movements that have generated individual verticalized figures on single themes (art, engineering, craftsmanship, gadgets, small and medium productions and so on) now we see hybrid figures capable of operating (not just knowing how to operate) in a more active way on the production scene. Such a change is not only the result of technique or sensitivity, but a way of acting that has been able to generate a result greater than the sum of its parts. Awareness of the tools and design by virtue of these.

6. Conclusion

The intertwining of specific artisan knowledge and the technological updating offered by digital manufacturing systems opens up to growth common, allowing the craftsman to take advantage of an amplified production system, and the activities to demonstrate an increasingly punctual public service.
By offering a critical eye to the good practices of knowing how to do in relation to the important social aspects and the union between those consolidated artisan qualities with the enabling technologies of Industry 4.0, the way will open for the definition of a new product social innovation, modeled on the needs of the citizen, guaranteeing the flexibility of digital manufacturing processes. The skills developed and systematized in this way will be able to generate improvements and implications also within the scientific community which will therefore be aware of the potential inherent in the urban and social fabric. The activities as they have been distributed and described, contribute to the implementation of the specific objectives and the achievement of the expected results described with the aim of directing the results of the Research in favor of those realities, whether they are artisanal SMEs or less mature, who can thus be able to experiment with tools, models and products that are both sustainable and compatible with the levels of complexity, flexibility and efficiency that increasingly characterize the contemporary landscape and that are gradually invalidating the traditional ones. With particular attention to the relationship established between the digital craftsman and his role as producer, the figure of the 'Maker' is placed in a context that no longer sees him as just a customer of an instrument market, but an active part of a production sector which has spread its production potential to everyone. An open, distributed and (still) free scenario, which nevertheless carries with it the weight of the moral, ecological and civil responsibility of a power that has long declared its potential.

Abstract | The aim of this study was to explore the joint structures used in traditional furniture to develop innovative designs and crafts that involve alternative materials or different processing methods while preserving the nail-free, mortise and tenon methods of traditional furniture. A total of 12 craftsmen were recruited using a participatory design approach and were invited to attend a three-month design workshop. Progressive guidance was given in three stages. First, several practical activities were arranged for participants to practice fabricating conventional mortise and tenon joints and to exercise their design awareness. Next, participants were asked to experiment with various wooden components to construct joints using available materials and material processing tools. Finally, participants proposed and implemented their designs based on their practice and exploration in the first two stages. To illustrate the reinterpretation of traditional crafts, three of these products were presented and described that best satisfied the study objectives.

KEYWORDS | JOINERY, CRAFT, FURNITURE DESIGN, TRADITIONAL KNOWLEDGE

1. Introduction

1.1 Craft in modern design

In the era of technology, with the influences of contemporary values, machine-made products, and quality expectation, craftsmanship has become a medium for designers to communicate their ideas (Kermik, 2012). Marcel Wanders, Jurgen Bey, and Jaime Hayon are designers that have aimed to make craft design more accessible. Contemporary art critic Risatti (2007) noted that 'if craft is to survive in the twenty-first century, it must take itself understood as a way of bringing objects into the world that is meaningful in and of itself. The value of the craft is within the capacity of the artisan to manage every step of the process (Sennett,2008). Moreover, traditional craft is more than a source of inspiration; it enables craftsmen to realize their design potential.

1.2 Joinery: material and making

Joinery originated in ancient Egypt and the Hemudu area, and joinery systems developed separately in the West and East (Wang, 2013; Korn, 2003). Among the various types of joining methods, mortise and tenon joints are often deemed essential in furniture making (Wang, 2013).

The function of joints in wooden furniture has evolved from structural to decorative. For example, furniture makers must consider wood grain or colour matching (Seike, 1977; Chen, 1997; Booth & Plunkett, 2014). Studies on structural strength have revealed that the joints of wooden components are the most vulnerable part of a piece of furniture, and thus determine its loading capacity (Nandanwar, Naidu, & Pandey, 2013; Tankut & Tankut, 2011). Numerous factors affect the loading capacity of the structure. For woodworking joinery, the type of wood and type of mortise and tenon joint must be considered.

1.3 Material selection and inspiration

Structural joints are crucial for determining the loading capacity of furniture (Nandanwar, et al. 2013; Tankut & Tankut 2011). Thus, when innovating in joinery woodwork, craftsmen and designers must apply knowledge of traditional joinery and innovate on the basis of these traditions, which involve a philosophy of crafting. Crafting can be viewed as a manifestation of culture; in addition to altering the substance, crafting adds meaning to the product (Tin, 2007). Materials are a crucial part of crafting. The primary materials and their composition and assembly comprise material manipulation (which is also known as crafting). The properties of materials must be considered during the crafting process (Ingold, 2013).

Through interdisciplinary collaboration, and technology and science of other domains, Contemporary craftsman Trish Belford used interdisciplinary collaboration, material integration and contrast, and other technologies to demonstrate the role of craft in the development of new technologies and the reform of aesthetics (Ravetz, Kettle, & Felcey,

2017). Sörensen (2016) reviewed studies on design and materials and listed four complementary material selection methods: deductive reasoning (selecting materials using a material properties database), inductive reasoning (reviewing existing products that can provide new solutions), similarity (searching for alternatives in property configuration documents), and inspiration (randomly reviewing a series of materials or products) (Ashby & Johnson, 2013). Sörensen (2016) also proposed displaying materials in example products to encourage designers to consider the characteristic and meaning of materials when selecting them in the creation process (Karana, Hekkert & Kandachar, 2010). These studies have highlighted a close relationship between material properties and the crafting process as well as a relationship between materials and the function and performance of the product (Lenau, 2002; Karana, Pedgley, & Rognoli, 2013).

Considering the importance of furniture structure and our attempt to bring innovation to traditional crafts and make breakthroughs, this study, which is the beginning of a series of studies into creativity, followed the following principles: 1) the value of design is derived from a craftsmen's exploration of materials and 2) inspiration can be obtained from traditional craftsmanship. The aim of the study was to find feasible alternative structures and forms on the basis of craftsmanship, materials, and structure. This study explored the use of wood materials for furniture innovation by testing creative structural joints of woodworking joinery both theoretically and practically. Wood is chosen to be the material here because it is an organic material that the grain reflects meteorological changes in air, humidity, and sunlight.

2. Method

This study adopted a participatory design approach, and a design workshop was held for drawing, conversations, contemplation, planning and design, project development, and prototype construction (Martin & Hanington, 2012). The four complementary material selection methods proposed by Ashby and Johnson (2013) and the materials selection advice provided by Karana, et al. (2010) were referenced for observing and recording participants' design behaviour and outputs.

The workshop was held during the summer of 2017 in Taiwan through the National Taiwan Craft Research and Development Institute (NTCRI), a government agency in Taiwan that promotes tradition crafting technologies in contemporary design. Two workshop meetings were organised each week for 3 months (16 hours in total). The 12 participants (six novices and six experts) were all Taiwanese and were aged 24 to 53 years; five participants were female and seven were male. Four professional instructors (one experienced designer and three craft technology instructors) assisted the participants in the workshops.

Table 1. Participant Background

Participant code	A	B	C	D	E	F
Gender/age	Female, 47 years	Male, 34 years	Male, 50 years	Male, 31 years	Male, 49 years	Male, 53 years
Participant background	5 years of knitting experience ; woodworking novice	8 years of design experience ; 3 years of woodworking experience	20 years of woodworking experience	5 years of design experience ; woodworking novice	15 years of art experience ; woodworking novice	Woodworking novice
Participant code	G	H	I	J	K	L
Gender/age	Female, 32 years	Male, 37 years	Female, 35 years	Female, 25 years	Female, 24 years	Male, 25 years
Participant background	Woodworking novice	5 years of woodworking experience	8 years of woodworking experience	5 years of design experience ; 3 years of woodworking experience	1 year of art experience ; woodworking novice	3 years of design experience ; 3 years of woodworking experience

2.1 Practical Procedure

The workshop comprised three stages. The first stage comprised preparatory practice and concept introduction. During the second stage, material combinations were tested and selected. The final stage was for idea implementation and prototyping. The research framework and flow are illustrated in Figure 1. Details of the process are described in the following sections.

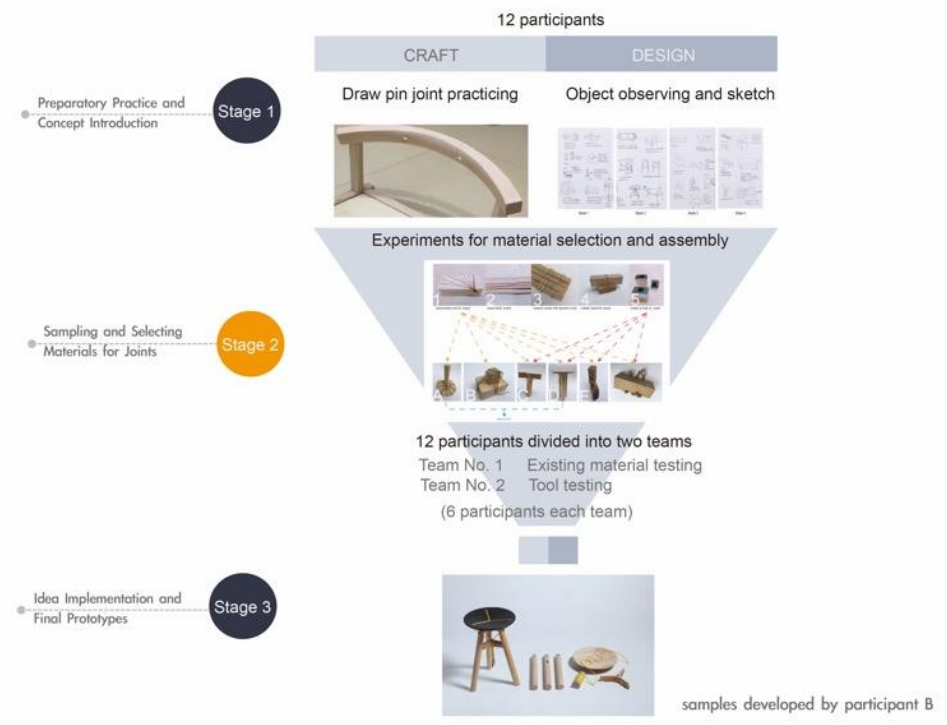

Figure 1. Research framework and flow.

2.2 Stage 1: Preparatory Practice and Concept Introduction

During the first stage, the participants were coached by three craft technology instructors to practice fabricating the cogged scarf joint which was redesignated by the technology instructors to separate the common dovetail tenon in furniture structure. The cogged scarf joint enables simple furniture disassembly and were frequently used in the curved rails of round-back chairs produced during the Ming Dynasty. The introduction of this concept and the hands-on practice prepared the participants for the material selection and design development in the second stage. The design instructors asked the participants to complete a text-and-picture-based perception exercise over a 4-week period. To perform this exercise, the participants first chose a theme (e.g., plants, insects, and pastries) and then completed a sketch and a description of at least five objects each week (Figure 2). The objective of this exercise was to encourage the participants to observe the compositions of objects. Moreover, drawing these objects enhanced participants' observational memory and perception, thereby preparing them for the material selection during the second stage.

Figure 2. Record of the 4-week design perception exercise of Participant B.

2.3 Stage 2: Sampling and Selecting Materials for Joints

The objective of the second stage was to guide participants to consider the properties and limitations of wood as a material and enable them to experiment with different material combinations and wood processing tools to develop structural joints that preserve the essence of joinery and yield a strong structure. The key components of this stage were material selection based on design and crafting knowledge, structure assembly, and crafting process arrangement. Five professional instructors (three technology instructors, one design instructor, and one researcher) provided consultation to participants on material selection, structure assembly testing, and crafting during the 8-week period of Stage 2. Then, the researcher and the design instructor assisted the participants to develop their design concept from the various combinations tested.

First, the researcher and the design instructor explained the concepts of material joints and testing to the participants. Next, the participants were divided into two equally sized groups in accordance with the additional nonwood materials, brought by the participants, and various material processing tools. The researcher also asked the participants to record their material selection and assembly processes in words or in drawings similarly to the perception exercise completed in Stage 1.

The researcher and the design instructor subsequently guided the participants to consider not only the component crafting process for the wood tenon and mortise structure practiced in Stage 1 but also those of other joint structures commonly used in wood furniture. Participants in the first group used materials such as cotton threads, leather strips, and plastic strapping to join wood or combine other materials with wooden components. Participants in the second group used material processing tools to investigate alternative methods for fabricating wooden joints. For example, an ax can be used to split wood at different angles, and a laser cutter (provided by NTCRI) can be used to cut wood and perform a series of wood bending tests.

Finally, the participants chose five joining methods for their design and development based on the material selection and assembly samples. The orange and red dotted lines in Figure 3 indicate the designs that a material assembly sample can be developed into. The orange dotted line denotes the use of thread for tying the materials in designs A to F in assembly sample 1. The red dotted line denotes hole drilling or colouring in designs C to F as in assembly sample 5. In addition to receiving advice from the researcher and design instructor regarding the development of the material assembly samples, participants were assisted by the technology instructors, who predicted the structural strength of the designs based on their experience and offered suggestions on material processing. Group discussions were organised several times to help participants to determine the most feasible structure based on the structural test results of their chosen materials.

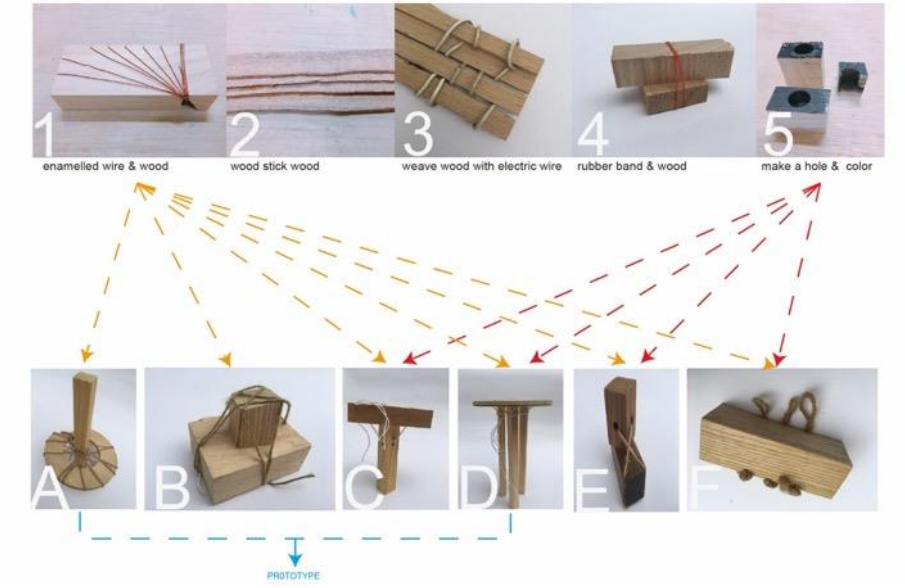

Figure 3. Designs using of the five material combination samples developed by participant B.

2.4 Stage 3: Idea Implementation and Final Prototypes

Participants individually developed a series of assemblies comprising wood and other materials. For example, some participants used various types of thread and weaving and knitting techniques to create a wooden assembly in which structural joints were formed through friction between the materials. One participant used shrink materials to assemble the structure. In total, 12 products were fabricated in the workshop, and the prototypes and primary material assembly approaches are described for each group in Table 2.

Table 2. Prototypes and primary material assembly approaches (participants were coded alphabetically)

Group 1: Existing material assembly testing	Code	A	B	C
	Photo			
	Approach	Hole drilling and knitting	Tying with thread and hole drilling	Tying for fixing
	Code	D	E	F
	Photo			
	Approach	Thermoplastic films	Wax sealing	Fixing by using a corrugated cardboard structure
Group 2: Joint structure tested after using material processing tools	Code	G	H	I
	Photo			
	Approach	Surface baking treatment	Wood splitting using an ax	Surface baking treatment
	Code	J	K	L
	Photo			
	Approach	Surface spraying	Surface processing by using Eastern gouache	Surface laser cutting

The results indicated that participants in Group 1, who used available materials for testing wood joints, were more successful than their counterparts in Group 2 in generating prototypes that met the objective of the experiment. The participants in Group 2, who tested assemblies after using material processing tools, had insufficient time for the convergence of their designs because the materials for assembly testing must first be

processed using tools. Consequently, only Participant L managed to produce a prototype in the time provided. Regarding the prototypes created by Participants G to K, the material processing was applied either partially or fully to the prototype surfaces and the structures of their finished products used the traditional mortise and tenon joints.

3. Illustrations

Prototypes that best satisfied the requirements of this study are illustrated herein. These three cases are from Group 1, and they used binding, knitting, and tying for materials assembly. Records of these prototypes are presented as follows:

3.1 Case 1: Bind

The participant used tying by thread and hole drilling to replace the traditional joint structure. After several discussions with the researcher and the four experts, the participant applied the method to a traditional Taiwanese wooden stool (Figure 4); holes were drilled on the surface of the seat for the legs, which could be easily assembled or disassembled through binding.

Figure 4. Traditional Taiwanese wooden stool (Photo: Author)

This participant applied the binding method to the stool, which reduced the labyrinth of crafting joints with multiple angles (i.e. A, B, and C; Figure 4). To stabilise the structure, the participant retained the traditional cross lap joint structure (D) and the leg joint (B). In addition, the participant used binding to secure the seat and the legs, thus improving the sustainability of the wooden stool by enabling the user to replace worn threads (Figure 5).

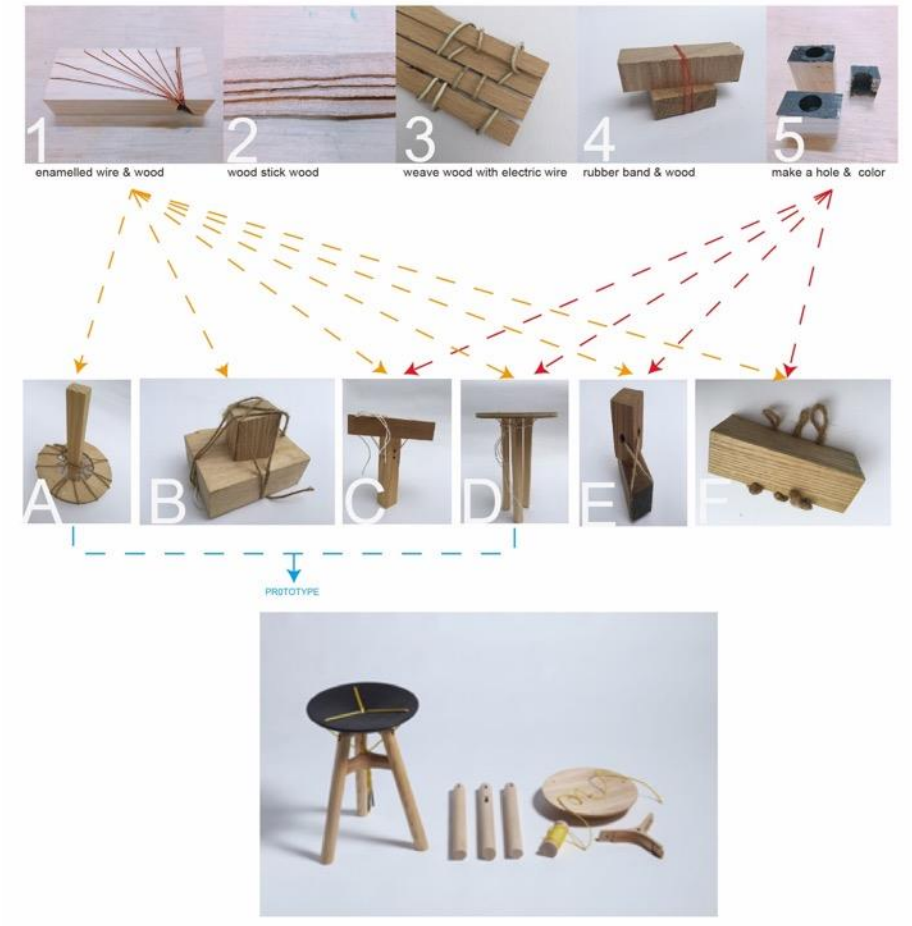

Figure 5. Series of experiments for material selection and combined with ramie and cotton thread and final prototype. Photo: Participant No. B /NTCRI.

3.2 Case 2: Knitting

This participant applied knitting expertise to material assembly samples and tested various threads (e.g., cotton thread, aluminium wire, and wool yarn) and knitting styles to identify the approach that best stabilised the wood joints. Several trials revealed that joints created using knitting with wool yarn or cotton thread yielded the optimal joint stability. This joint comprised continuous intermeshing loops, and wool yarn and cotton thread yielded greater friction than aluminium wire, thus improving the stability of the joint.

After discussions with the researcher and the four experts, the participant decided to implement this approach in wooden panels joined using a dovetail joint (Figure 6). The participant tested the feasibility of the structure using material combination samples 2 and 3 (Figure 6) and proposed a desk design (Figure 7) as the prototype.

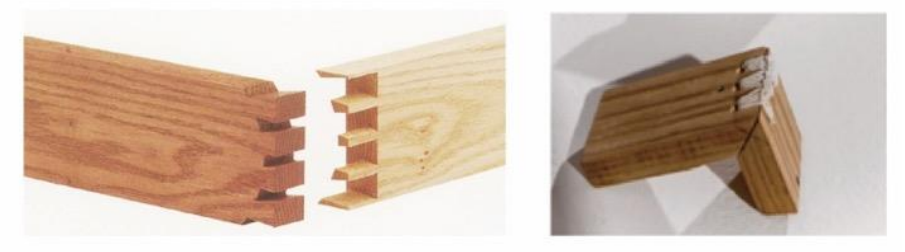

Figure 6. The dovetail joint structure (left) generally applied in making cabinets and tables. Photo: Author.

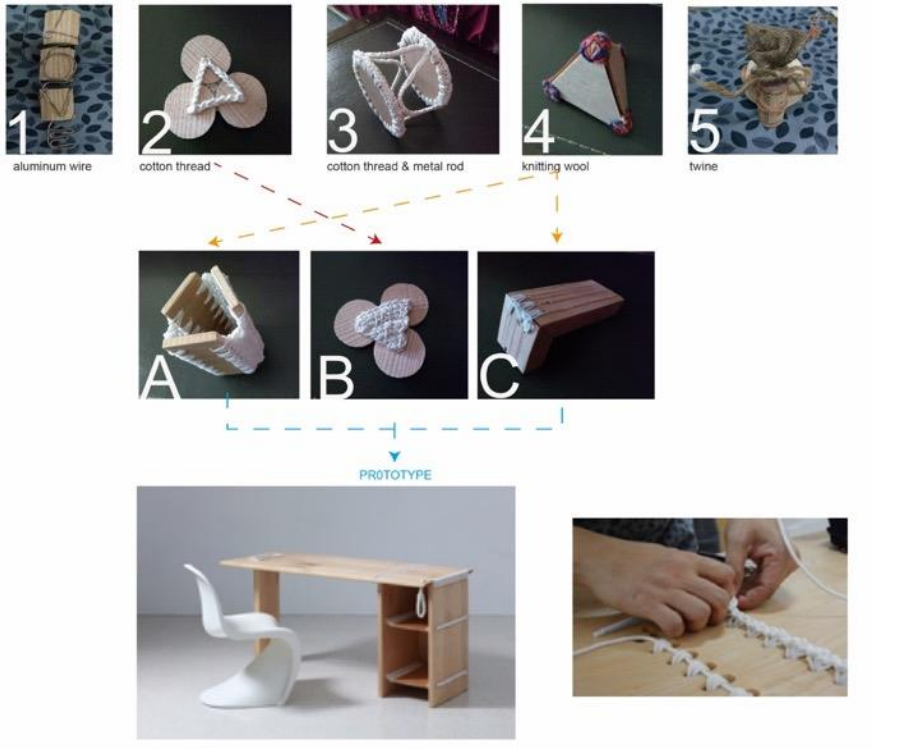

Figure 7. Series of experiments for material selection and knitting connection and final prototype. Photo: Participant No. A / NTCRI.

3.3 Case 3: Tying

This participant's material combination sample contained long strips of materials (e.g., wide paper strips, plastic strapping, and bamboo strips). The participant first drilled holes in the wooden materials and then tied the materials together for testing. After discussions with the researcher and the design instructor, the participant implemented the design in a Taiwanese farmhouse-style bench. Similarly to Case 1, crafting the joints of the bench legs is relatively challenging. Because this participant was an experienced carpenter, the design instructor encouraged the participant use materials other than threads to secure the joints. Following this suggestion, the participant developed a tying method that creates friction between long leather strips and wood. This tying method enables the user to fully disassemble the bench (Figures 8 and 9).

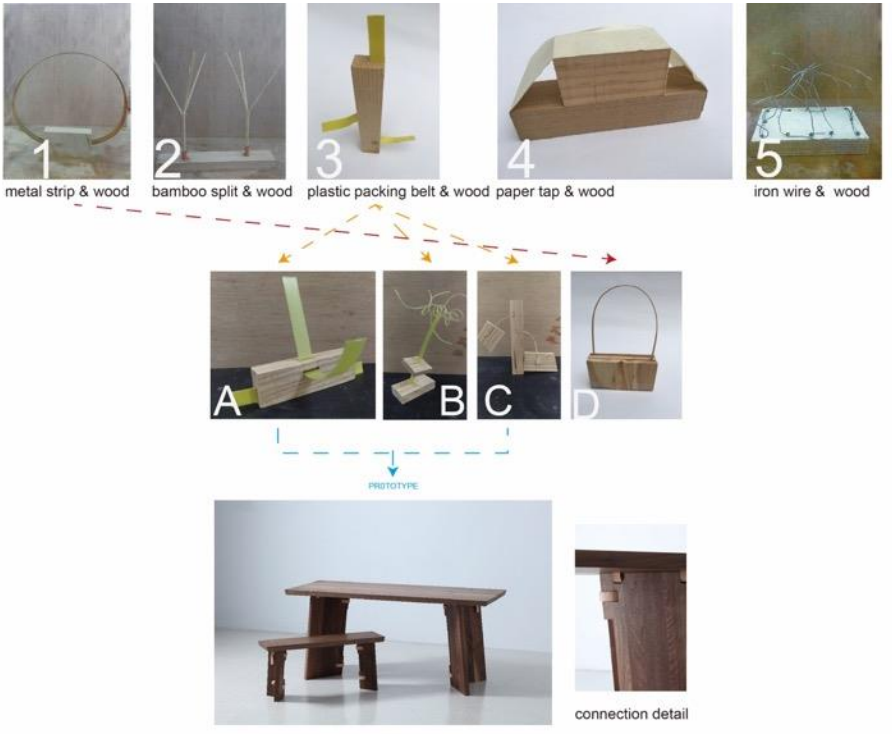

Figure 8. Series of experiments for material selection and wearing ways and final prototype. Photo: Participant No. C / NTCRI.

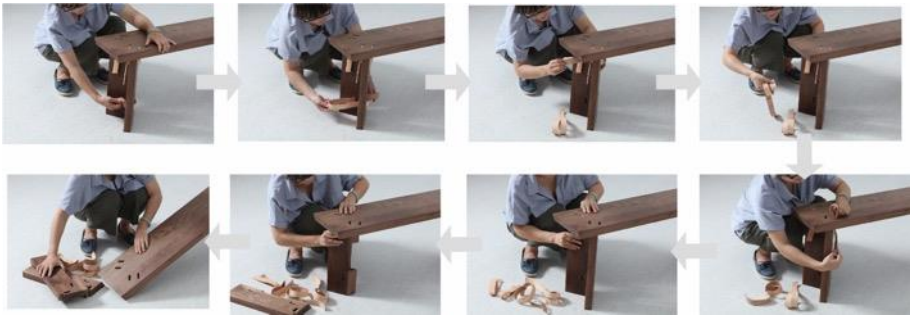

Figure 9. Disassemble and assemble process. Photo: NTCRI.

4. Findings from Implications of design

This was a pilot study exploring alternative materials combinations for traditional furniture joinery. When developing their designs based on trials of material assembly or material processing tools after discussions with the researcher and experts, most of the participants proposed designs associated with traditional furniture structures or designs that incorporated concepts of traditional furniture structure. The three cases presented in this paper were all inspired by the structure and form of a traditional mortise and tenon joint. The use of leather strips and cotton threads to replace the mortise function is one unexpected example.

For participants who were experienced carpenters, processing wood was not a difficult task. By contrast, their challenge was to supersede their existing thinking and training as craftsmen. Participants required knowledge and experience to identify appropriate materials. For example, in Case 1, although the overall assembly should have been secured by thread according to the study requirements, the traditional cross lap joint was retained as the primary supporting structure of the prototype to meet the load-carrying capacity of the wood stool.

Among the participants in the second group, who performed trials of material processing tools, only one (Participant L) successfully completed the task. This participant performed trials using a laser cutter to cut the surface of wood. They then used bendable wood pieces—cut using the laser cutter—to replace the hinge structure of a cabinet cover panel. This idea was inspired by design plans obtained from Pinterest (www.pinterest.com), and the technology instructor approved its feasibility. Although this approach was not novel, it used modern tools and approaches to replace the conventional method, thus providing a new direction for this study. The other participants applied splitting, baking, and Eastern gouache to the surface of wood; because they spent most of their time on material processing, they failed to develop a concept that related to joint structure. These participants completed only one product using their material processing method. Therefore,

the researcher should have clearly instructed the participants on applying the processing tools during the implementation stage.

5. Reflections and future work

The selection of a material combination requires repeated practice, which is crucial in this study considering that the focus was on traditional wood joinery, the physical properties of which render it a relatively challenging material. Conversations between participants and the researcher and design and technology instructors as well as conversations among the participants played a critical role during the implementation stage; these discussions enabled the participants to clarify their concerns regarding the appropriateness of materials combinations. Moreover, participants were able to obtain suggestions from others and perform trials. No participants were experts on all subjects, but they could identify a participant familiar with their chosen materials.

When exploring the material combination, the participant in Case 3 identified methods to exploit material properties such as firmness, friction, and flexibility. In future studies, material properties can be explored and applied to the fabrication of novel wooden joinery structures. In addition, methods for incorporating digital-aided design and digital manufacturing into the crafting process and design brainstorming should be considered to expand the value of traditional crafting technology. The experiences of this design workshop on material combinations and selection will be applied to bamboo, metal, and ceramic crafts. Subsequent studies in this series will explore the ability of craftsmen to apply bentwood and digital crafting to joint structures and to innovate on the forms of these joint structures.

Amorphous Stacks: A Low-Tech Construction Method for Jointless Cast Structures

Liqiong Huo, Jongwan Kwon,

[a]Rhode Island School of Design
huoliqiong@gmail.com, jkwon03@risd.edu

Abstract | The project explores an experimental fabrication method to reinvigorate masonry techniques and stereotomy (stone-cutting) construction. It introduces amorphic blocks cast from a pressure-driven scaffold system, stacked into four archetypal structures to examine the method's performance and applicability. The low-tech, self-explanatory, and hand-craft aspect of this construction method contributes to greater accessibility and the potential for widespread application in areas devoid of technology and resources.

KEYWORDS | FORMATION OF FLUID MATTER, AMORPHOUS GEOMETRY, GEOMETRIC STACKING SYSTEM, JOINTLESS STRUCTURE, DIY MASONRY CONSTRUCTION

1. Introduction

This paper explores the creation of a new dry-stacked system of an interlocking family of distinct amorphous units cast in fluid material. The use of a stacking system in constructing structural and ornamental architectural features with discrete and modulated units is evident throughout the history of stonemasonry. From the Roman concrete arches stacked with mortar to the dry-stacked Inca stone walls and the extensively used mass-producible brick constructions of modern architecture, the art and science of stacking systems in masonry have evolved both structurally and aesthetically, reflecting the increasing needs of high efficiency and new aesthetics in the culture of building.

The current practice of stone masonry construction is divided into two broad categories according to the fabrication method: stone-cutting and solid-casting. Both categories have adopted innovative materials and construction techniques through research and practice while presenting different architectural applications. In the case of stone-cutting in masonry construction, many practices combine traditional craftsmanship with digital fabrication technology and structural analysis. *Cyclopean Cannibalism*, a research project led by Brandon Clifford and Wes McGee (2018), successfully translated the ancient construction methodology of Cyclopean masonry into a contemporary digital procedure with high accuracy and efficiency through the use of a six-axis robotic arm to carve each stone unit of a Cyclopean masonry wall. Other contemporary research on stereotomy has integrated digital computation in the design process. The *Sean Collier Memorial*, designed by Höweler + Yoon (2015), combined new digital fabrication methods, including computational graphic statics and robotic machine milling, to build a five-way vault geometry with traditional stonemasonry techniques.

Similarly, solid-casting construction has evolved with digital modeling and fabrication tools yet has strayed from a holistic approach by limiting the material's structural capability. Current experimental practice and forefront research in solid-casting tend to focus on developing computational techniques to produce complex geometries and visual aesthetics while overlooking the potential to accentuate the nature of the material and materiality. The application of cast stone continues to be used primarily for cultured stone and ornaments to mimic prehistoric aesthetics. Innovations in cast concrete are mostly limited to the cladding system, focusing on visual appearance rather than the construction process and structural integration. The *Broad Museum* in Los Angeles, designed by Diller Scofidio + Renfro, is characteristic of its parametric precast concrete façade composed of glass-fiber-reinforced concrete (GFRC) panels that were cast in digitally fabricated molds, showcasing a versatile and rapid prototyping workflow. While it combines the precast technique with complex geometry, the method requires a substantial supporting structure to hold up the cladding system. However, the current trajectory undertaken by architectural designers and researchers calls for more attention to exploring the materiality of fluid materials for casting. As Pier Luigi Nervi stated, although the casting of fluid material (i.e., reinforced concrete) has been used in architecture for over a hundred years, "few of its properties and potentialities

have been fully exploited" (West, 2017, pp.4). While the geometry of stereotomy (cutting) is limited to ruled surfaces since the generative surface follows the trajectory of the cutting blade, the plasticity of the casting material allows an extraordinary variety of forms with non-developable surface geometries with the introduction of flexible formworks. With the exploration of stacking units' surface geometry, there is the possibility of a new construction method that supports itself (without mortar). The accessibility of fluid materials around the world also suggests its great potential to be popularized by larger user groups, specifically those in remote regions that have limited construction resources and technology.

Another challenge of contemporary masonry construction, as well as in other material constructions, arises from the perishing value of craftsmanship in the culture of making. As the stereotomic problem has become creating "a whole that must be made of various parts" (Sanabria, 1989, pp. 266), the fabrication system has gradually transformed into a standardized mass production process that produces uniform building units, such as bricks, resulting in maximal productivity and economic benefits. However, these two trajectories of mass production and technology-oriented development have rarely reflected the inherent value of traditional masonry that resides in its technical virtuosity. Mass production and advanced digital technology not only remove the marks of the builders' hands from the artifacts but their required high level of expertise and background knowledge further hinder the popularization of the techniques and constrain access to only specific user groups with status and resources (Eglash et al., 2004); people from remote or isolated areas with limited resources have restricted opportunities to use these new techniques. This phenomenon reveals the social challenge of the contemporary construction paradigm and the need to address the broader socio-economic problems and propose sustainable solutions.

How can modern architecture reinvigorate tradition without losing the value of craftsmanship? What are the opportunities in fabrication to challenge accessible means of construction? In exploring of an approach alternative to those centered on technologies, this study addresses the challenges of the lost value of making and the urgent social need for accessible construction techniques in underdeveloped places. This paper reconsiders the casting technique in masonry construction and reexamines the materiality of fluid materials to offer new possibilities in expressing the intrinsic qualities of the material. Through prototyping and speculative design, it reflects on a new understanding of an integrated and reciprocal relationship between material and human experience in the course of making.

This paper presents three primary objectives on the subject matter after an introduction to the fabrication methodology. Firstly, it examines the applicability of the new construction method by prototype testing four archetypal structures. Secondly, it discusses the potential and limitations of the method based on the results drawn from the first section, followed by reflections on future exploration and development. Finally, it proposes a possible application of the technique to solving real-life architectural problems. By drawing results from physical models, this investigation aims to contribute to the diversity of possible research approaches to masonry construction methods.

2. New Masonry Construction Method

2.1 Casting From Flexible Formwork

This study adopted plaster casting as the primary fabrication technique to engage the thinking of matter as a participant in generating form. There are several advantages to casting as a fabrication method. It is a relatively simple construction method that requires very little technological support, offering the possibility of construction in situ. Common materials for casting, such as concrete and plaster, are highly accessible and can be executed. The plasticity of the fluid materials also facilitates the subject of this study. The casting materials' transitional phase between liquid and solid states allows the manipulation of their form. Their fluid nature implies a self-activated form-finding process that responds to their surroundings. As the mold mostly constrains the casting outcome, the utilization of a flexible mold (fabric and inflatable materials) is crucial in the sense that it implements the materials' intrinsic qualities instead of discounting and overpowering them. Paired with the use of the flexible mold (in this case, the latex balloon), the materials "actively seek the shape of their own stability in the gravitational field" (West, 2017, p.6). As Mark West noted in his explorative research on the use of fabric formworks in concrete casting, the materials in play are "alive": they arrive at the final geometry in a kinetic way, engaging in "a kind of formal self-invention in real-time" (West, 2017, p.6). Plaster was adopted as the material for casting prototypes due to its similarity with concrete and soil, yet with a shorter curing time.

The study uses the surface geometry of stacking units manipulated by a flexible scaffold system (Figure 1) to create an interlocking system without the use of mortar. Under the same method, architectural applicability was tested using the construction of three phasing prototypes: the fabrication of a column structure, an inclined column and wall structure, and a conical wall structure. The geometry of the latex balloons filled with liquid plaster was manipulated by external pressure generated by a cubic scaffold system to create organic forms with concave and convex surfaces (Figure 2). The formwork also utilized temporary fabric support in place of possible wooden falsework. Between the amorphous blocks, the seamless fitting of concave and convex surfaces behaved as joinery that interlocked the masses. During the casting process, each unique block became a part of the scaffolding system for the succeeding one, providing sufficient friction for structural stability. The realized form reflected the means of its construction from the geometric properties of each individual and mutually-responsive unit. This simple construction method would allow users to build it themselves with minimal equipment. Embracing the characteristic of irregularity in material crafts, no specific patterns of the arrangement were employed intentionally during the fabrication process. This flexibility in making opposes the strict uniformity required by mass production and the high precision prescribed by technology, offering greater freedom of creation and accessibility.

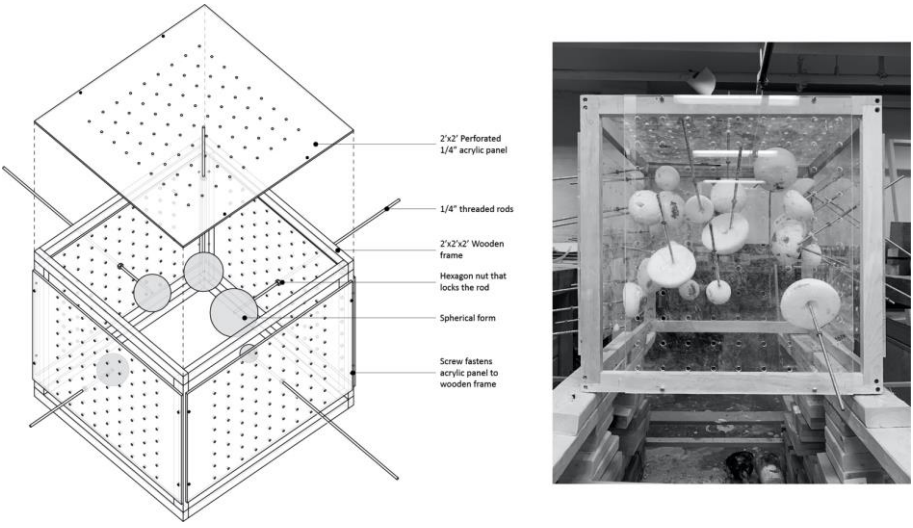

Figure 1. Pressure-driven scaffold system.

2.2 Pressure-Driven Scaffold System

A customizable pressure-driven scaffold system was designed to fabricate the stacking structure (Figure 1). Builders were able to construct the entire structure solely by this system without additional tools and machines. In addition, it was composed of simple components that could be disassembled and reassembled easily, providing an advantage of mobility. As a type of force, pressure can take various forms and effectively transform the shape of soft matter. In this study, spheres of different radii were used as the pressure impetus. The perforated panels of the formwork enabled the spherical force to enter the cubic scaffold system from the exterior in axial directions in order to apply force onto the plaster volume, while the grid pattern established a customizable and controllable system for axial pressure in multiple configurations. This scaffold system also included a sheet of heavy-duty fabric, which was placed and secured around the wooden frame. The fabric sheet helped to offer temporary support for the structure, creating a flexible platform for manipulation. The plaster volume confined in the balloon was left to cure after it found its own shape of static equilibrium through the back-and-forth adjustments of pressurizing and depressurizing. Thus, the geometric outcome of the stacking units was subjected to both the imposed pressure and the surrounding context (gravitational force). The combination of the prescribed parameters and the open-ended factor implies a more holistic construction method than an entirely prescriptive one.

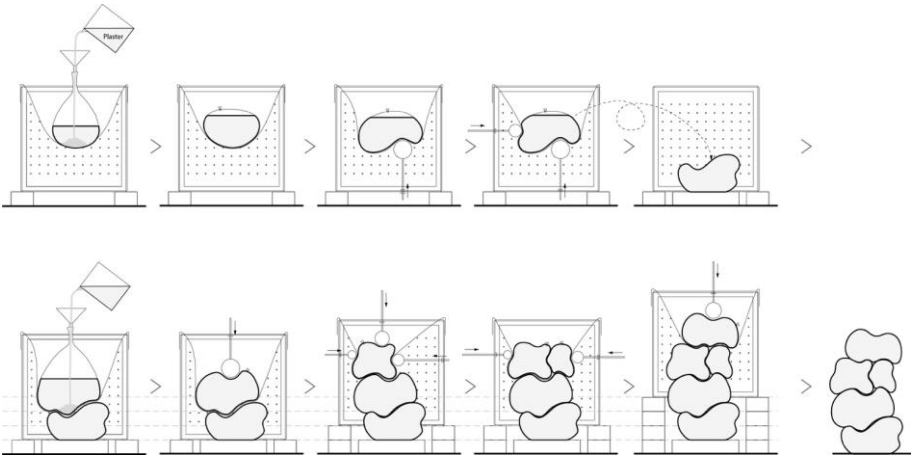

Figure 2 Fabrication sequence of stacking blocks.

2.3 Surface Geometry as Joinery

The connection between each block was achieved by its surface geometry without the use of mortar cement. After casting one block, the next block was cast on top of the previous one, which became part of the scaffold for the succeeding block. Thus, a concave surface on the previous block would form a convex surface on the latter one, and vice versa (Figure 1). The seamless fitting of concave and convex surfaces increased the contact surface area between the two blocks and provided greater friction for structural stability. The concave and convex geometry also behaved as the joinery system that interlocked the two blocks by eliminating the rotational movement. The greater the depth of the concave and convex surfaces, the stronger the anchoring function they perform. Moreover, a larger distance between the centers of gravity of the two blocks would not only require a greater surface curvature, but also the weight of the upper unit to stabilize the structure (Figure 3). This connection system shares similar principles with those of Inca masonry techniques; Inca stonemasons utilized the friction between precisely-cut matching faces of neighboring stones as a connecting mechanism. However, the surface geometry's behavior as joinery in this study differs from the Inca prismatic ones in its amorphous geometry, contributing new aesthetics to the conventional masonry practice.

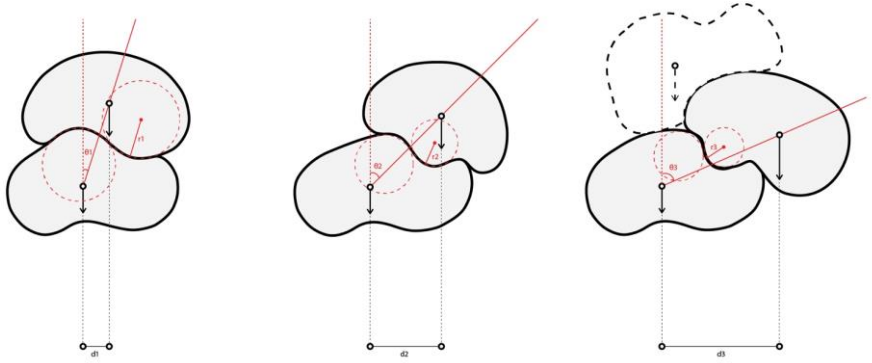

Figure 3. A larger distance requires a larger degree of surface curvature and the weight of an upper stone for structure stability. (r1>r2>r3, d1<d2<d3, Θ1<Θ2<Θ3).

3. Structure Prototypes

3.1 Column Structure

The architectural applicability of this construction method was tested through three major studies that included four archetypal structures: a vertical column, inclined columns, an inclined wall, and finally, an inclined conical wall. The first study investigated a 6-feet vertical column structure constructed by a 2'X2'X2' cubic scaffold to examine the applicability of the new method (Figure 4). The vertical column was composed of 10 unique plaster blocks with an average size of 1'X1'X1'. This size of the stacking block allowed an approximately 20 minutes for the workable form before it was left to cure, which would take up to 24 hours. The structure eventually attained its global static equilibrium when the final keystone was set in place. With this fabrication method, the stacking structure achieves static stability only after completing the assembly process.

The process of finding the global equilibrium was one of trial and error, a course that was more intuitive than computational or systematic. This constructive process is a concern that resides in most handcraft traditions, which has been solved mainly by the accumulation of experience. Recent research has integrated computational modeling and solver-based simulation to test and revise the structural performance before fabrication, establishing a more efficient design workflow that ensures a successful outcome. Examples include the use of the *Grasshopper* component to calculate the center of gravity in the *Quarra Cairn*

research project completed through a collaborative effort between the Massachusetts Institute of Technology and the University of Michigan (Clifford et al., 2017). This limitation of the innovative construction technique appeals for further explorations and research on designing a solver-based computational program that can simulate the optimal positions for each stacking unit in advance.

The paradoxically stabilizing function of the keystone in the amorphous stack recalls the argument stated by Charles Perrault in the 17th century and mentioned in Richard Etlin's introduction to *Stereotomy: Modern Stone Architecture and Its Historical Legacy.* Perrault described stereotomy as being based on the paradox that the practice employed "the weight of the stone against itself by making it hover in space through the very weight that should make it fall down" (Fallacara & Stigliano, 2012). Stonemasons in different eras have addressed this problem from different approaches according to the available contemporary technology and knowledge. Inca stonemasons confronted the problem by solely using the weight of stones to achieve stability (Protzen, 1985), whereas Roman builders avoided this problem by using temporary wooden formwork and thick mortar joints (Sanabria, 1989). A majority of recent research on stereotomy has centered on integrating technology that relies on auxiliary support and joinery systems, as in Roman architecture. This study, however, takes an approach aligned with that of the Inca builders, where the form solves the problem of physics with its mass and geometric characteristics, resulting in a direct and responsive relationship between form and structure. This approach considers the matter's resistance to weight as a virtue rather than as an obstruction to be overcome (West, 2017).

Figure 5. Detail views of the 6 feet column structure.

Figure 4. Prototype of a 6 feet column structure.

3.2 Inclined Column and Wall Structure

The second study continued to develop the fabrication method to resolve the static equilibrium of inclined columns and wall structure by adding two fixed planes to the formwork. As each amorphic block offsets the others in a linear fashion, it will form a leaning structure with an angled central axis. Two fixed planes were added to the top and bottom of the scaffold to prevent the structure from collapsing. A key knob was attached to each panel, acting as a pin joint to prevent blocks from sliding and rotating. A piece of fabric, which was later removed, was secured to the two panels at a certain angle, functioning as temporary support for the inclined structure during the fabrication process. Besides the adjustment of the scaffold system, other fabrication processes remained the same, including the use of latex balloons and casting in plaster. As the last unit was cast in place, the inclining structure reached its static equilibrium and no longer needed the fabric support.

This study examined one-foot tall column structures at two different inclining angles: one at 20 degrees (Figure 6) and the other at 45 degrees (Figure 8). Both structures maintained a static equilibrium after all blocks were cast and the fabric was removed. The success of the two prototypes suggests the wider potential of this technique's application in architectural construction. After two inclined column prototypes, this study proceeded to explore the possibility of applying the technique to construct an inclining surface structure by examining a half-foot tall inclining wall structure at 30 degrees (Figure 11). In this wall structure, the relationship between the amorphic blocks was no longer a one-to-one dialogue but multi-directional and dynamic. Each amorphic block not only related to its vertical neighbors but also to the horizontally adjacent ones. This network interrelation with multiple directionalities added extra structural stability to the wall section.

Figure 8. One-foot tall inclined column structure at 45º.

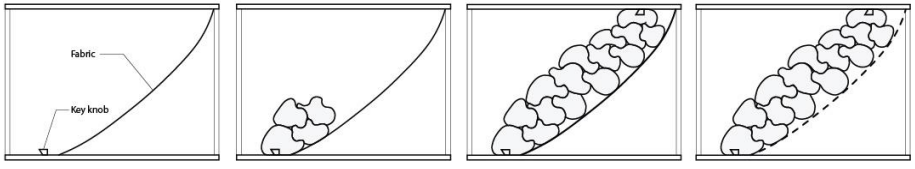

Figure 10. Sequence of prototyping the inclined column structure at 45º.

Figure 11. Prototype of the half-foot tall inclined wall structure at 30º.

3.3 Inclined Complex Wall Structure

The third study proceeded to fabricate a larger-scale prototype with highly complex geometry to further examine the potential of the construction technique. The increase of scale led to a strengthening of the scaffold's structural capabilities to face the challenge of large scale constructions. An inverted conical surface was chosen to introduce geometric complexity (Figure 12). The entire structure was constructed by a 3'X1.5'x3' scaffold and consisted of 104 stacking units of 1/2'X1/4'X1/4' plaster blocks, with 20 degrees of inclination. The structure successfully held itself up; however, it failed after removing the supporting fabric due to the deformation of the fabric caused by overweight. Another leading reason was the disproportional relation between the scale of each stacking block and the entire structure. The scale of each stacking block was demonstrated to be too small for the scale of the overall structure, which resulted in a much larger number of the units that led to a higher probability of collapsing in this dried-stack structure without mortar. In conclusion, this complex prototype proves the potential of this construction method in building organic forms and dynamic structure. The result of this prototype also suggests that a complex geometric structure and larger scale constructions in question require more thoughtful planning of scale and material usage than a column structure in order to be free from collapsing.

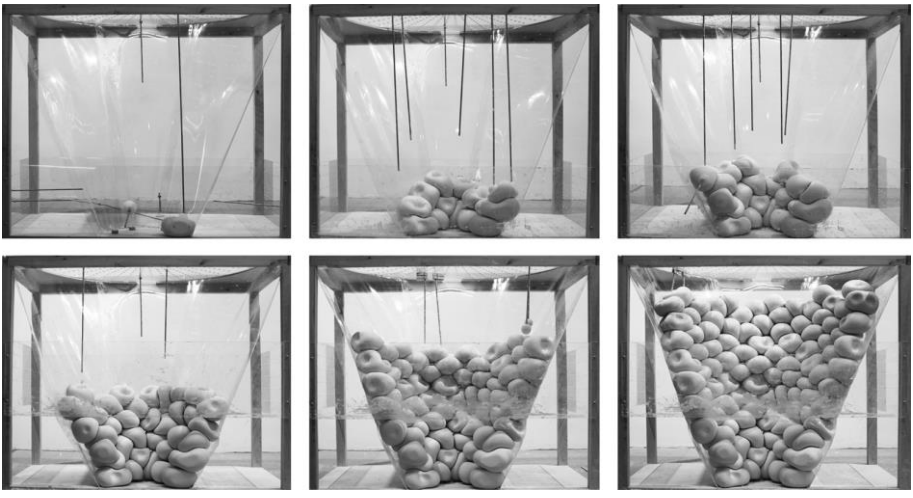

Figure 13. Sequence of prototyping the 3'X1.5'X3'inclined conical wall structure.

Figure 14. Detail view of the inclined conical wall structure.

4. Discussion and Conclusion

The prototype testing results of the four archetypal structures prove the validity and applicability of this innovative fabrication technique and suggest its potential in constructing a structure of greater complexity. During the prototyping process, several variables emerge to be crucial for the effectiveness of the construction: the surface curvatures of the concave and the convex, the inclination degree, the relationship between the total number of units within each self-standing structure, and the structural capacity of the scaffold system when facing the challenge of large scale construction. A conjecture can be drawn from the testing result of the four archetypal structures that there is a right domain of ratio between the structure's total volume and its unit count for the practicability of the construction method.

Utilizing the fluid property of liquid casting, this construction method reflects the relationship between form and physics in the fabrication process. The use of the surface geometry of each block as the joinery system eliminates the need for additional adhesion or mechanical joints, which establishes a direct and responsive relationship between form and structure. Although the interlocking system improves structural stability, the center of gravity must be monitored to achieve a global equilibrium. The intuitive aspect of the search for global equilibrium during the fabrication process presents an opportunity to incorporate a new computational program. This combination of craftsmanship and digital computing could potentially yield a hybrid model in which technology and human hands are codependent.

The design and the prototype examination of this fluid-cast and pressure-driven fabrication method rethink the potential of liquid-casting materials and the curing process in constructing organic forms and structures. Its low-tech and crafts-based attributes inform itself of a non-standardized and self-explanatory construction method that could be adopted in areas of limited resources, technology, and skilled-builders. The widely accessible casting materials, including concrete and plaster, allow users to build structures in places with difficulties in transportation, such as high mountains or remote islands. The DIY aspect of this technique blurred the boundary between users and builders by lowering the prerequisites and skill demands. With the support of computational parametricism and algorithms, the hand-built approach gradually abolishes in favor of robotic arms. By utilizing the virtue of the fluid material, this fabrication method's flexibility and plasticity challenge the standardization of mass production and the prescriptive design, offering greater freedom of creation and accessibility. This exploration presents an alternative approach to masonry construction, inheriting the legacy of past knowledge to imbue the making tradition with greater accessibility.

An Exploratory Study about Communicating 4D Printing between Product Designers and Manufacturing Engineers

Faten Ezrin Azhar*, Eujin Pei,

Brunel University of London
* FatenEzrin.Azhar@brunel.ac.uk

Abstract | 4D Printing is an emerging technology that combines Additive Manufacturing and stimuli-responsive shape memory materials to produce freeform parts that can evolve over time. In this paper, we suggest that using conventional sketches to communicate 4D Printing does not fully convey the design intent. This paper provides evidence of poor communication between Product Designers and Manufacturing Engineers when describing 4D Printed parts. Literature review highlighted that very little studies have been carried out to investigate the communication of the shape transformation process. The study found that the marks made on paper were spontaneous and unpredictable. For example, participants used random colours, arrows and shading. Time was indicated by using 'symbols' and splitting this into two separate sketches to define the differences in speed. The main study involving fourteen pairs of Product Designers and Manufacturing Engineers aimed to capture the participants' gaze and behavioural activity during sketching using OBS Studio Software and with a Wacom Bamboo Tablet. To track the Product Designers' and Manufacturing Engineers' sketching process, the participants were asked to view an animation that showed the shape change behaviour. Next, they were asked to make annotations to specify the geometric relations using symbols, dimensions, angle, alignment and symmetry on the sketch to communicate the shape change behaviour of the 4D Printed parts. In summary, this study has found that a framework could be further developed as a guideline to communicate the shape changing behaviour of the 4D Printing process. The main contribution to knowledge is to enable Product Designers and Manufacturing Designers to communicate the use of 4D Printing during the idea generation phase.

KEYWORDS | 4D PRINTING, COMMUNICATION, SYMBOLS, PRODUCT DESIGNER, MANUFACTURING ENGINEER

1. Introduction

The fourth dimension of 4D Printing refers to the element of 'time' where parts can transform or reshape (Tibbits et al., 2014; Pei et al., 2017). 4D Printing uses materials that can remember and recover to a programmed deformation when parts are exposed to an external stimuli (Ge et al., 2014). During the early stages of the design process, sketches or drawings are often used as a visual communication tool (Eitz et al., 2012). In this context, the medium for communication is important because poor representations could potentially lead to confusion (Alcaide-Marzal et al., 2013). Sketches are often the most effective way for Product Designers and Manufacturing Engineers to capture their thoughts and ideas about a design solution. According to Baronio et al. (2016), sketching and dimensioning is required as requirement for designers and engineers before they proceed to use Computer Aided Design (CAD) to create two-dimensional (2D) drawings or three-dimensional (3D) models. Figure 1 shows an example in the use of symbols referring to a technical drawing that shows information about a hydraulic circuit system. We can identify the moving parts of the system such as the motor and the pump unit by means of arrows and other associated symbols.

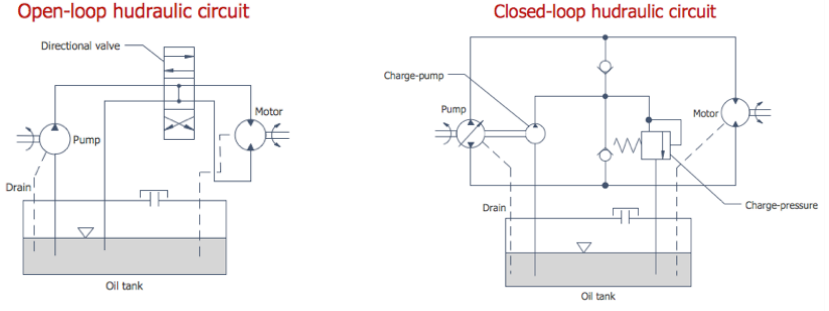

Figure 1. Example of symbols used in hydraulic circuits.

Our earlier work identified existing challenges for 4D Printing to be communicated during the early stages of the design process. We found that participants made random marks on paper and there were no recognised or established symbols available to explain or represent 4D Printing, especially for shape transformations. For this study, the use of symbols was chosen so that visual communication of the core message could be easily conveyed. This paper describes the study in which the main objective was to evaluate whether the use of established symbols could be effectively used to communicate the shape change effect of 4D Printed parts.

1.1 Shape Changing Behaviour in 4D Printing

Nam and Pei (2019) classified 4D Printing shape-change behaviours into three categories, namely basic shape change, complex shape change, and a combination of shape change. In

this research we focus on eleven different shape-change behaviours, including folding, bending, rolling, helixing, twisting, waving, curling, curving, topographical change, buckling and expansion. According to Nam and Pei (ibid), a fold is a sharp curvature caused by deformation along a crease. As shown in Figure 2, it is different from a bend which is a more evenly distributed deformation of a material along the deflected area that creates the curvature. Rolling is a different behaviour, in which the shape moves by turning over and over on its own axis. On the other hand, twisting is dominated by in-plane stretching. A helix is a type of smooth deformation in which a curve occurs in a three-dimensional space. Buckling is characterized by a sudden sideways failure of a structural member subjected to high compressive stress or force. Curving is the amount by which the surface of a geometric object deviates from a flat plane. Topographical change results in a distorted shape that resembles the physical features of a ground terrain. Expansion and contraction shape-changing behaviours are based on a shape-memory cycle. The waving behaviour results in a shape that has undulating features or a wavy up-and-down form. Lastly, curling produces a similar resultant effect as curved creases along a continuous surface. There are also notable differences in the degree of shape change (Nam & Pei, 2019). Curving, twisting and helixing shape-change behaviours have deformation angles occurring in the hinge area; while bending, topographical and twisting shape-change behaviours have a deformation that results in less than 360°. If this is more than 360°, the deformation is classed as rolling, buckling or curling.

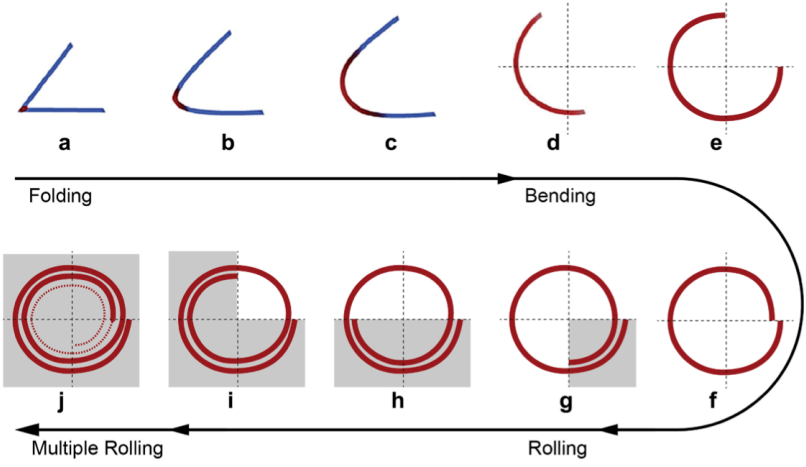

Figure 2. The differences between folding, bending, rolling and multiple rolling (Nam & Pei, 2019).

1.2 Symbols and Icons

The word ‘icon’ is derived from the Greek word ‘eikon’ which refers to ‘the image’ (Yan,

2011). Empirical studies about iconography and symbols can be regarded as a subgroup of visually descriptive or figurative language (Wagner, 2015). Both icons and symbols are used to represent pictographs which are graphs that encode words through the medium of representation (Bottero, 2004). Icons usually represent only visible things, whereas symbols represent the idea. Icons are defined as clear graphical representations with little need for translation. On the other hand, one has to learn what a symbol stands for, as it is not similar to what it represents (Rogers, 1989). Icons are also restricted to the graphical representation of objects and one can easily understand what they refer to.

2. Empirical Research

The main objective of this study is to evaluate whether the use of symbols could be effectively used to communicate the shape change effect of 4D Printed parts. A set of 33 symbols representing the shape-change effect of 4D Printing was first created. An initial study involved one post-doctorate designer and one post-doctorate engineer. This was created to ascertain the total duration of the task that would be required, as well as to clarify the sequence of activities. We found that the pilot study took an average of one hour to complete. For the main study, we recruited fourteen designers and engineers from the Department of Design, College of Engineering, Design and Physical Sciences at Brunel University London in the United Kingdom and also from the Faculty of Engineering, Universiti Teknikal Malaysia Melaka, Malaysia. In this focus group study, the participants needed to have a background in either design or engineering. In terms of the limitations of this study, our main concern was that the number of participants who took part in the focus group was small (n=14), and it was also difficult to recruit participants who had a good knowledge of 4D Printing.

The focus group consisted of three main tasks, involving a (1) 'Classification Test', (2) 'Visual Test' and (3) 'Development Test'. For the 'classification test', the participants had to match the text that described the shape-change behaviour with three symbols that were provided. This task introduces the eleven 4D Printing shape-changes, so as to enable the participants to understand the 4D Printing deformations (Figure 3). The participants were asked to match each symbol with their corresponding shape-change behaviour for this first task and the correct matching and error rates were collected. For the 'visual test', the participants had to rate each of the three symbols according to good, average and poor. For this second task, we wanted to find out which symbols had the best preference. Lastly in the 'development test', the participants were asked to further suggest two other alternative symbols for each of the 4D Printing Shape-Change behaviours. The purpose of this task was to allow participants to create alternative designs of the symbols.

Before starting the task, the participants were briefed about the purpose and the procedure of the study. They were asked to read an information sheet before completing a consent form to participate in this study, in line with the university's ethical process. The participants

were not timed and they were given sufficient time to complete all the tasks. The average time required to complete the focus group was approximately an hour (Figure 4).

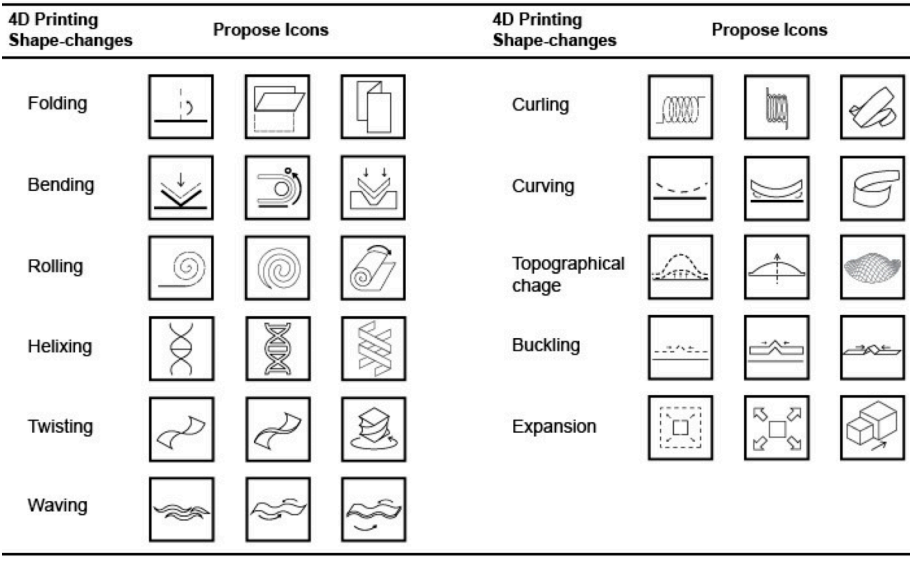

Figure 3. Symbols designed for the 'classification test'.

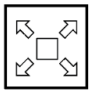

Figure 4. Participants undertaking the experiments.

3. Analysis and Results

The results of Task 1 'Classification Test' are presented in Table 1. The first column showed the representative symbols of the shape-changes symbols for folding, bending, rolling, helixing, twisting, waving, curling, curving, topographical change, buckling and expansion or contraction. The second column showed the correct answer that the participant should answer. And the third column showed the total of participant that choose the correct answers. The table refers to the Participant number. It was found that 8 out of 14 participants received correct answers in Task 1. The 8 participants matched correctly all of the symbols with 4D Printing shape-change behaviours. In addition, we also found that folding, rolling and helixing were correctly matched by all participants. Conversely, 'topographical change' was the symbol that was the worst matched which 4 out of 14 participants answered it wrongly. Next, 'curving' received 3 out of 14 participants who matched incorrectly and they were confused with the 'topographical change' symbol.

Table 1. Task 1 required participant to match the set of symbols with the corresponding 4D Printing shape-change behaviour.

Proposed 4D Printing Shapeshift Symbols			Answers	Total Correct
			E Folding	14/14
			H (Bending)	12/14
			K (Rolling)	14/14
			G (Helixing)	14/14
			J (Twisting)	13/14
			A (Waving)	13/14

			I (Curling)	12/14
			B (Curving)	11/14
			C (Topographical change)	10/14
			D (Buckling)	12/14
			F (Expansion)	12/14

From this task, it was found that folding, rolling and helixing had the highest score (14 participants who matched the icons correctly). Twisting, waving and expansion had the next highest score (13 participants who matched the icons correctly). Bending, curling and buckling had 12 participants who matched the icons correctly. Curving had 11 participants who matched the icons correctly, and Topographical Change had 10 participants who matched the icons correctly, giving this icon the poorest score.

For Task 2 'Visual Test' there were 3 symbols for them to choose, as shown in Table 2. The participants had to rate their most preferred symbols, with the '1' rating referred to good, '2' rating referred to average, and '3' rating referred to poor. From this task, the most agreed symbols for all 4D Printing shape-changes behaviour were found. Among them, the folding shape-change behaviour received the best results with 14 of the participants agree with the middle symbol as shown in Table 2 being their most preferred and easiest to understand representation. However, the first symbols received only 5 agreements. Similarly, in the second column referring to the bending shape-change behaviour, 10 participants rated the middle symbol as their most preferred representation. From this exercise in Task 2, a summary of their preferred choice of symbols is shown in Table 2.

Table 2. The results of the most preferred symbols selected by the participants to represent the 4D Printing shape-change behaviour.

4D Printing Shape-changes	Agreed Symbols	Total Correct

E Folding				n=14
H (Bending)				n=10
K (Rolling)				n=12
G (Helixing)				n=11
J (Twisting)				n=11
A (Waving)				n=13
I (Curling)				n=12
B (Curving)				n=12
C (Topographical change)				n=13
D (Buckling)				n=13
F (Expansion)				n=13

For Task 3 ‘Development Test’, the participants were asked to create two symbols with their own idea to represent the 4D Printing shape-changing behaviour. With 14 participants participating in the study, generating 22 symbols per participant, a total of 308 icons were created. For this task, there was no restriction on the number of strokes, orientation or sketching style used to represent the 4D Printing shape-changing behaviour. However, the

symbols had to be drawn in black and white and had to be sketched within the boxes that were provided. This ensured consistency across all participants and the space given within the box ensured that the icons created could be seen when shown within a tight constraint. The results indicated that there were significant similarities among engineering participants where they usually included a known symbol that represented the angle, or force, etc. Conversely, most designers only used arrows and shading to define the features, especially in the 'topographical change' shape-changing behaviour. In order to completely analyze the 308 symbols generated, we observed and scrutinized every single symbol, and made 3 distinct observations for each symbol as summarized in Table 3.

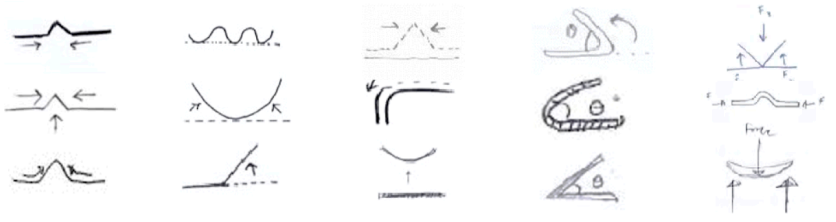

Table 3. Task 3 required participant to create two icons based on their own idea.

4D Printing Shape-change behaviour	Observations
Folding	1. Arrow to indicate direction and folding sequence.
	2. Symbol for view angle.
	3. Dash line to indicate axis of folding.
	4. Preferred 1D or 2D shape to indicate folding symbol.
Bending	1. Symbol 'F' to indicate force.
	2. 'G' indicate as Gear in bending machine.
	3. More than one arrow to indicate direction
Rolling	1. Curve arrows to indicate roll direction
	2. 3D shape to represent rolling shape.
	3. Rolling dash line.
Helixing	1. Used double line to indicate helix shape.
	2. Cross line and dash line.
	3. Curve arrows to indicate movement.
Twisting	1. Arrows circle around symbol to indicate twist
	2. 3D shape to represent twisting.
	3. Curve up and down arrows to indicate twist movement.
Waving	1. Wiggly line represent wave shape.
	2. Shadings to differentiate changes shape.

	3. Arrows to indicate wave movement.
Curling	1. Single curling line.
	2. Thick curl line represent 3D curl shape.
	3. Arrows to indicate curling movement.
Curving	1. Show two views represent shape changes.
	2. Dash semi curve line above straight line to indicate curving shape.
	3. Semi curve 3D shape.
Topographical change	1. Some of participant indicate differentiate movement with colour.
	2. Shading differentiate different surface
	3. Dash line differentiate different surface and movement.
Buckling	1. Two arrows facing each other to indicate force.
	2. 'F' symbol to indicate force.
	3. Sharp edge to indicate high compressive stress.
Expansions	1. Four or more arrows in every corner.
	2. Two different size of box to indicate expansion.
	3. Different size of circle to indicate changes of size.

3.1 Discussion of observations

From the observation of task 3 and task 2, there is some mismatch found between participant's sketches and rated symbols proposed by the researcher indicating shape-change behaviours. For example, most participants used arrows, angles, and sequences of folding either in 1D or 2D shape to indicate folding symbol as presented in Table 3. However, in task 2, the highest agreement received for the agreeable symbol was in 2D shape and did not show any angles and arrows, as shown in Table2. Therefore, from this observation, the researcher can conclude that it is easier for the participants understanding a 2D shape symbol including arrows and angles to represent a shape-change behaviour of 4D Printing.

Task 2 - The highest agreements received for any symbol which was in 3D shape and did not show any angles and arrows.

Task 3 - Most participants used arrows, angle and line either in 1D or 2D shape to indicate 4DP Shapeshift behaviour.

Figure 5. Some of symbols proposed by researcher indicating 4D Printing Shape-changes behaviour..

From the observation of task 3 and task 2, there is some mismatch found between participant's sketches and rated symbols proposed by the researcher indicating shape-change behaviours. For example, most participants used arrows, angles, and sequences of folding either in 1D or 2D shape to indicate folding symbol as presented in Table 3. However, in task 2, the highest agreement received for the agreeable symbol was in 2D shape and did not show any angles and arrows, as shown in Table2. Therefore, from this observation, the researcher can conclude that it is easier for the participants understanding a 2D shape symbol including arrows and angles to represent a shape-change behaviour of 4D Printing.

4. Conclusions and Future Work

Sketching facilitates the communication of ideas in the early stages of the design process. There are very few established methods available to communicate the shape-changing behaviour of 4D Printing. Our study has found that the use of icons to represent 4D Printing shape-changing behaviours could potentially help product designers and manufacturing engineers apply proper representations to communicate with each other during the design stage. For future work, we will develop a more thorough framework by applying the symbols in Table2 into the actual design process and observe the communication when designing 4D Printed parts.

About the Authors:

Faten Ezrin Azhar She is a full-time PhD student in the Design Department at Brunel University of London. She is supervised under Dr. Eujin Pei who is a Programme Director for the BSc Product Design; and Programme Director for the BSc Product Design Engineering courses at Brunel University. Ezrin holds a Master's degree in Art and Design from University Technology MARA Malaysia. Being awarded the chance to study further in her field at the Brunel University London is an incredible opportunity for her and she intend to seize wholeheartedly without reservation. Currently, she is doing her research on 4D Printing regarding her research topic 'Improving Communication between Product Designers and Manufacturing Engineers when Designing 4D Printed Parts. This research aims to propose the use of symbol that can support communication between designers and engineers, particularly when designing parts for 4D Printing. Communication in design incorporates the elements of great virtual design and takes things a step further by considering the way users understand visuals.

Dr. Eujin Pei Eujin leads the 4D Printing Research Group with his interest focusing on Additive Manufacturing and Smart Materials. He gained hands-on experience as a Research Fellow at Loughborough University, Brunel University London and at the University of Southampton. He was a Visiting Scientist at Vaal University of Technology and at the Central University of Technology in South Africa. His active involvement in professional Memberships enable him to be a step ahead in policies and emerging technologies. He is an active Member of the British Standards Institution TDW4/8 that develops Standards such as BS 8887 for Design for MADE; and BS 8888 for Technical Product Specification. He is a Member of ISO/JTC1/WG12 which develops standardization work for 3D Scanning and 3D Printing within the scope of Information Communication Technology. Eujin also regularly participates in ISO/TC 261/AHG 05; ISO/TC 261/AHG 06; ISO/TC 261/JG 74; and is a Member of ISO/TC 261/CAG Chairman's Advisory Group, and ISO/TC 261/JAG ISO/TC 261 - ASTM F42 Steering group on JG activities. As Convenor for ISO/TC 261/WG4, he oversees the work of ISO/TC 261 - ASTM F42 joint groups including ISO/TC 261/JG 54 Joint ISO/TC 261-ASTM F42 Group for Fundamentals of Design; ISO/TC 261/JG 57 Joint ISO/TC 261-ASTM F42 Group for Specific Design Guidelines on Powder Bed Fusion; ISO/TC 261/JG 64 Joint ISO/TC 261-ASTM F42 Group for Solid Modelling Support; ISO/TC 261/JG 70 Joint ISO/TC 261-ASTM F42 Group for Optimized Medical Image Data; and ISO/TC 261/JG 73 for Joint ISO/TC 261-ASTM F42 Group for Digital Product Definition and Data Management.

Abstract | Our daily life is surrounded by materials, but we are not necessarily aware of them. However, their importance in human society is undeniable at many levels. This paper views materials as objects of dialogue which can move us towards a sustainable consumer culture and evaluates present alternatives based on the fourth industrial revolution. The paper focuses on practice-led research by a transdisciplinary group of designers and engineers, using agroindustry waste to bio-fabricate prototypes of everyday life objects. Several mechanical characterization methods have been applied to test permeability, flexibility, strength and absorption. The results have revealed both functional and aesthetic possibilities. Lastly, the paper concludes with a road map that analyses bio fabrication and circular economy alternatives in South America, to illustrate my vision that through plausible collective actions and policy change scenarios we can design new consumer choices.

KEYWORDS | WASTE REMEDIATION, BIOMATERIALS, CIRCULAR ECONOMY, EVERYDAY OBJECTS, BIOTEXTILES

1. Introduction

Materials are a fundamental part of our culture, but we are often disconnected and ignorant as to where they come from and how they are manufactured. Materials are part of a continuous, often disposable, behaviour network: we allow ourselves to buy, use and discard them. Materials are political, as their production and manufacture at low cost allows citizens to buy more and discard easily. This behaviour is not compatible with the actual earth we live in. There is an urgent need to develop sustainable strategies, rethink mass consumption, and plan according to real future scenarios throughout the entire supply chain. It's necessary to talk about materials' political agenda to support sustainable innovations and embrace brands to commit to move towards zero discharge of toxic chemicals in various industries. We are focused on addressing the fast fashion industry, as its one of the major polluting agents due to its vast overproduction of fashion items, the use of synthetic fibers, agricultural pollution, massive freshwater and ocean water pollution and soil degradation. This is a heated topic of discussion regarding global warming goals, even though there hasn't been any real action towards harder policies that lower industries' emissions within its full supply chain. These policies could include the creation of incentives to support new alternatives at a large scale to reduce petroleum as a main resource, or alternatives to cotton to decrease water consumption and electricity. Using natural dyes would reduce water pollution, acting local would decrease transportation. The consumer is also responsible for this impact and there is no sign that we want to change our consumption habits. Therefore, it's important to create competitive consumer choices by designing systems that economically support sustainable brands. The One of 17 SDG goals set in 2015 by the United Nations under the 'sustainable consumption and production patterns' goals, is to educate consumers on sustainable consumption and lifestyles, providing them with adequate information through standards and labels and engaging in sustainable public procurement, among others (UN, 2015). After 5 years trying to reach this goal, it doesn't seem like they will hit their mark by 2030.

On the other hand, sustainable material alternatives are increasingly being explored. We are living in the fourth industrial revolution. The first and second industrial revolutions harnessed water, steam, and electric power, challenging the traditional system of craft-based production. The third industrial revolution harnessed information technology and data analysis, giving birth to the fast fashion movement. The fourth industrial revolution is based on innovations across the physical, digital, and biological worlds, driving a new wave of change across the economy (Abnett, 2016).

Communities of makers, biohackers, designers, engineers, biologists, architects, and artists have risen up working collaboratively, with raw materials, observing nature and taking inspiration from ancestral wisdom and new technologies. Today, we can control the growth of microorganisms, fractionate matter, or purify ultra-cellular structures that by themselves have very interesting physiochemical characteristics (Carvajal, 2011). Furthermore, the textile industry innovation such as "Functional Fashion, E-Textiles, Smart Fabric, Smart

Clothing – is slated to be worth $3 billion by 2018 or $9 billion by 2024" (Suikkanen, 2019, p. 2). Moreover, initiatives to reduce the environmental impact of fabric manufacturing will likely increase those numbers even further. These practices also have a huge potential in fields such as packaging, fashion, architecture, and medicine, among others.

> "Although many of these new textile innovations are still at the early development stage, the sportswear and fashion industry is embracing the use of bio-based textiles and designers are beginning to challenge themselves to create entirely bio-based products" (Prahl, 2018).

As a result, a lot of research is being devoted into dyeing and chemical processing of biopolymers of value as textiles. Although not every biomaterial is able to become a fiber, there is plenty of research on plausible applications for the future. Thus, these techniques do not yet seek industrialization but alternative applications based on raw materials.

> "Brands are expected to announce partnerships with businesses that have figured out ways to make leather without cows, silk without worms, fur without animals and fabrics from recycled waste. Salvatore Ferragamo has been selling scarves made of orange fibers while Stella McCartney produced outfits made with vegan spider inspired silk for Adidas since 2017." (Wendlandt, 2017)

A more unusual waste stream is cow manure, as explored by Dutch designer and entrepreneur Jalila Essaïdi through her start-up Mestic. They developed technology to deconstruct manure and convert the cellulose into biomaterials including bioplastic, biopaper and bio textiles; "demonstrating that the most disgusting matter is inherently beautiful" (Essaïdi, 2017).

> "In addition to creating a fully biodegradable textile, this process helps reduce the production of harmful methane gas and can prevent the contamination of soil and water caused by intensive farming"(Prahl, 2018).

Although scaling these new innovations for industrial applications is a possibility, most of these initiatives have not come from big companies but from artists, architects, designers with limited capital, driven by material innovation in a holistic way. These initiatives have triggered a material revolution demonstrating how bio fabrication plays an important role in shaping the future. Neri Oxman, Associate Professor of Media Arts and Sciences at the MIT Media Lab, focuses her research on "the relationship between the built, natural, and biological environments" (MIT, 2019). She employs design principles inspired and engineered by nature, such as the famous Silk Pavilion installation in 2013, built at an architectural scale through biological fabrication. Another example is the Pavilion grown from mycelium made entirely from bio-based materials as a pop-up performance space at Dutch Design Week 2019 by designer and artist Pascal Leboucq in collaboration with Erik Klarenbeek's studio Krown Design. Mycelium has the potential to compete with plastics. They are naturally fire-retardant without need of using any chemicals, naturally hydrophobic and resist higher melting temperatures than plastics. Moreover, mycelium is compostable. (Lee, 2019)

In our process, we focus on local available materials as starting point to reimagine possible futures where new users and assemblages emerge. We ask ourselves, what if materials are engineered by citizens at home? What if these designs are made for communities living in remote areas? What if textiles are grown locally? How can bio-design contribute to a circular economy? How can we create alternatives that respond to future environmental threats? These questions trigger our designs, situating ourselves in different environmental conditions in the present and reimagining human-nature interaction.

2. Materials and Methods

The present work has been carried out by an interdisciplinary team comprised of designers and chemical, and materials engineering, using local agroindustry waste to create starch - based bio textiles. Our making process began by scaling up biomaterial Petri dish samples to a large-scale frame of one by one meter. Through practice-led research methods, we iterate through prototyping to apply functional and aesthetic solutions to materials. We focus on properties such as elasticity, permeability, flexibility, and most importantly, biodegradability - to produce creative design solutions applied to everyday objects. Moreover, workshops and conferences have been held to engage the community with the importance of rethinking material alternatives outside the laboratory.

2.1 The raw materials used in the process:

Table 1. Quantities used from cassava starch-based formula

Component	Working composition
Cassava Starch	5% w/v
Glycerin	2% w/v
Poly vinyl alcohol (PVA)	5% w/v

To prepare the base material, the compositions specified in Table 1 were used. Cassava starch was suspended in distilled water, and gelatinized at 80oC for 1h, under constant stirring. At the same time, PVA was dissolved in distilled water at 60oC. Both solutions, along with the glycerin, were mixed in an industrial blender and casted onto 1x1m molds, to me later dried in an industrial oven at 50oC.

We made physical and chemical material characterisation tests to determine its properties. We analysed its water absorption capacities with swelling tests in water. Its p morphology was assessed through Scanning Electron Microscopy (SEM). Its absorption was tested through measuring the contact angle of the biomaterial. The analysis of its mechanical properties was done through tensile strength tests and elongation at breakage.

2.2 Applying prototyping techniques to the biomaterial

The bioplastic based on cassava starch, PVA and glycerine formulation has been tested through practice-led research prototypes using techniques to form it in different ways such as sewing machine, laser cutting and thermoforming.

When sewing, a thickness between 1 to 2mm is best. When the material is less than 1mm, it becomes too thin and sticks to itself, behaving more like a plastic film. When the material is over 2mm, it becomes too thick and is difficult to manage, even with an industrial sewing machine.

When using the laser cutting machine cutting at thicknesses between 0.1mm to 2mm were successful. An aspect to consider with this fabrication method is that if there is too much detail on the design, the bioplastic tends to burn during the cut. Another aspect to consider is that if there is too much detail to cut, the bioplastic loses its stability. Its joints are assembled by joinery, defining connections between part edges in the assembly designed for laser cut. Other assembly biomaterial options are to glue pieces with water, or by a sewing machine.

Thermoforming works best with homogeneous materials. As not all these films are 100% homogeneous, when thermoforming some areas break more easily than others. While working with mostly homogeneous biomaterial with 1mm or more of thickness, the material thermoforms at 167°C with positive results.

Figure 1. Sewing prototyping technique.

Figure 2. First prototypes using laser cutting technique.

Figure 3. Material glued with water prototyping technique.

Figure 4. Thermoforming prototyping technique.

2.3 Workshops

One way in which we are rethinking material alternatives is through holding events such as workshops, talks and conferences. It allows professionals, academia and other practitioners from many fields to hold a joint dialogue about how materials and objects are managed in the present, and the need to be co-create new alternatives. Creating the spaces of conversation engages the community with material matters, even if some are in a still distant future or very hypothetical scenarios. Most of all, it opens up spaces for this work to take place outside laboratories, giving people confidence to engage hands-on with biomaterials, and understanding how to produce their own resources with waste.

Figure 5. Open workshop to learn bio fabrication from local raw materials.

3. Results

The process of reimagining plausible future scenarios through bio-materials raises more questions than answers. The agency of materials sets new interaction possibilities with waste and the way we buy and consume 'stuff'. The prototypes we create are not inspired by dystopian scenarios but by possible interactions within an uncertain future. Some examples are 100% biodegradable edible objects, garments that deliver data or work as probiotics for our body. They include garments that double as 'seed carriers' in case of nomadic emergencies, and materials that are entirely engineered and composted at home. These are only a few of the possibilities in reimagining material processes, manufacturing, use and adaptation to natural surroundings and potential future environmental threats.

3.1 Characterization methods

The results from characterization methods showed a high level of swelling the first 30 minutes, but then it loses its stability. As for its water absorption, the result shows little hydrophobic capacity. On the other side, its elongation test showed the bio plastic is able to expand to twice its original size. Furthermore, the film shows different breakage stress values due to its non-homogeneous result. Finally, it is shown through its degree of swelling

and absorption that the film is not as stable in an aqueous medium, thus natural fibres can be added to the formulation to improve this characteristic.

3.2 First tests

At first, we carried out research tests with different foods from which starch could be extracted such as sweet potato and cassava. After selecting the best Petri Dish samples, we tried to scale them to 33x25cm trays. After a few iterations varying the mixtures and the starch extraction base, we were successful with cassava starch. We began to perform more tests only with cassava but varying percentages of glycerine, starch and PVA. After a few tests we could obtain bioplastic variations. The tests showed the resulting material can be as flexible as a plastic bag, others more resistant as semi-rigid packaging, and in other cases have a more leather-like appearance. Furthermore, we tried shaking the mix before drying, obtaining a foamy appearance on the film. We also started to test with natural dyes. We used cochineal dye found in Andean local communities, where a very small quantity adds strong colours to the film. We mixed the cochineal dye with cream of tartar and water, adjusting the amounts to test colour intensity and water variations.

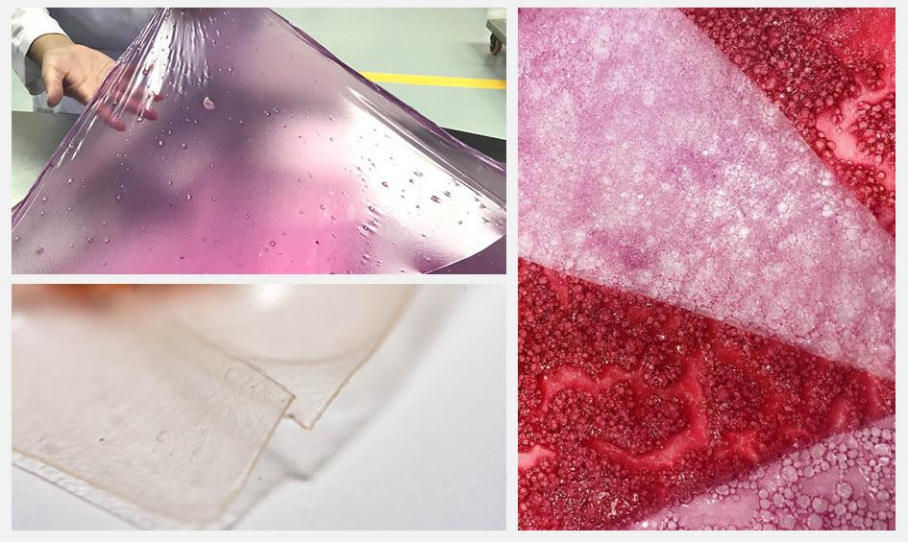

Figure 6. Cassava starch tests showed the resulting material can be flexible as a plastic bag (a); if using more amount of material have a more leather-like appearance (b); or if shaking the mix before drying a foamy appearance is obtained (c).

Figure 7. Color tests using cochineal dye found in Andean local communities.

Once we had a homogeneous result on the 33x25cm trays, we were able to scale the formula to a cassava starch film of 1x1 meter. The scaled films still present some degree of inhomogeneity but they have been improved through iteration that allowed us to start making real-scale prototypes. We went through an experimental process adding different dyes such as *juglans neotropica*, moringa, rose stem, and others. Also, we applied different densities to the trays to try various thicknesses.

Meanwhile, we also started carrying out tests with orange peels by extracting pectin. These materials haven't been characterised nor have mechanical tests been done, but we are continuing research through prototyping to understand its potential applications.

Figure 8. First test on 1x1 meter cassava starch film.

3.3 Bio materials applied to everyday objects

Biodegradable packaging is one of the potential applications for bioplastics, as we continue to phase out single-use plastic and paper bags from our lives. Our culture is moving slowly but contagiously into a conscious mindset that 'things' do not go away after throwing them away. Technologically we are already there on bio-based alternatives such as starch, wheat, banana, mycelium, or chitin; but our culture needs to catch up to demand competitive changes in the industry. This biopolymer based disposable packaging made from waste can also be produced and disposed of in environmentally sustainable ways. "They represent a possible shift away from plastics that can help detach humans from our reliance on fossil fuels" (Kandelin, 2019).

What if biomaterials are able to preserve food fresh longer, change color according to food freshness, be eaten, planted, composted or even add flavour to food?

Figure 9. Cassava starch bag.

Figure 11. Pectin based fruit packaging.

Figure 12. Cassava starch popcorn packaging

Figure 13. Cassava starch hotdog packaging.

Figure 14. Cassava starch French fries based on McDonald's packaging.

The fashion industry is slowly changing but mass consumption still needs to catch up. “An estimated 50 million tons of clothing are discarded every year, and most of it will not biodegrade in a landfill” (Farra, 2019). What relationships should be built with consumers and clothes in order to add sustainable values to what we wear? These prototypes are inspired by this question: garments that give us data about our environment, edible clothes with added vitamins, multifunctional dresses, and ‘seed carrier’ garments. All of these prototypes reimagine the way we make our clothes: grown locally, made from agro-waste, or fabricated in local centers with open source designs that can be downloaded anywhere, and finally, eaten or composted at home.

Figure 15. This cassava starch swimsuit represents plastic garbage islands in the sea. The data represents 2018 patch between Central America and Europe (Law, 2019).

Figure 16. Cassava starch gloves offering sking benefits such as hydration, removes scars and spots.

Figure 17. Cassava starch with native seeds, serving as a seed carrier textile in case of emergencies were communities have to move more nomadically in a plausible future.

Each year, “more than 640,000 tonnes of nets, lines, pots and traps used in commercial fishing are dumped and discarded in the sea every year” (Laville, 2019). No matter how deep scuba divers search, fishing nets are found in the sea all over the South American coasts. These prototypes are based on objects that are able to be discarded and biodegrade gradually. For this reason, pectin-based bio textiles have been used for fishing nets, which resist water longer. Other accessories such as a hammock suggest crafted objects to be used while travelling, made from waste.

Figure 18. Pectin-based fishing net.

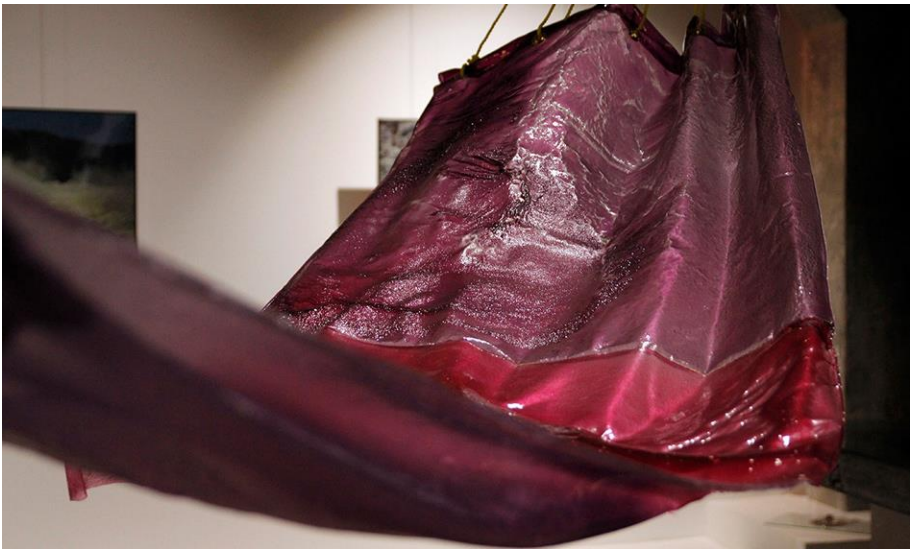

Figure 19. Cassava starch hammock.

4. Conclusion

Bioplastics formulations presented in this paper show their exciting potential to be applied to everyday objects. However, it is necessary for our society to better understand the potential of these nature-based technologies, and to change behaviors and practices prioritising renewable life, standardized new systems and healthier interactions between us and our planet. The system that we live in today is not sustainable for the earth. We need to create models where humans imitate nature, changing our urban metabolism into circular relations with materials and energy within healthier cities.

> "The ways in which goods, water, commuters, or food move through the urban ecosystem determines a city's health and sustainability within larger regional and global natural systems". (Eberlein, 2018)

Thus, the materials revolution can contribute to a more circular economy "based on the principles of designing out waste and pollution, keeping products and materials in use, and regenerating natural systems" (Macarthur, 2017).

The collaboration between academia and business will accelerate research to be applied to mass production. While our practice-led research inside academia is to create plausible applications, the industry can invest according to its interests, migrating its supply chain into sustainable solutions. According to CGS studies, "more that 50% of generation Z are willing

to pay more for a sustainable product" (CGS, 2019). It will not only be about market incentives for greener products but also that consumers finally demand it worldwide.

Collaboration between disciplines is essential to develop a design and science-based approach, able to embrace complex systems and simplify them through fresh perspectives and navigating ambiguity. It allows the problem to speak through interdisciplinarity, facilitating understanding and making information more digestible. Furthermore, research through design facilitates spaces of dialogue that provide agency to materials through diverse scenarios. When the public can visualize a potential reality, they are more able to embrace innovation and engage with conversations that cross science, art, politics, geography and biology. While all these disciplines seek sustainable futures, design uniquely contributes to research through product, services and experiences that imagine sustainable concepts for multiple audiences.

So, where is all this going? After analysing increasing alternatives within bio fabrication, I created a future road map based on this materials revolution. The aim of the roadmap is to describe the path from the present state towards a future vision providing a summary of various factors on different levels at a glance (Itälä et al, 2015). Throughout this roadmap, I analyse the present of bio fabrication and circular fashion alternatives in South America. Then I draw my vision based on plausible collective actions and policy change scenarios that design a version of new consumer choices.

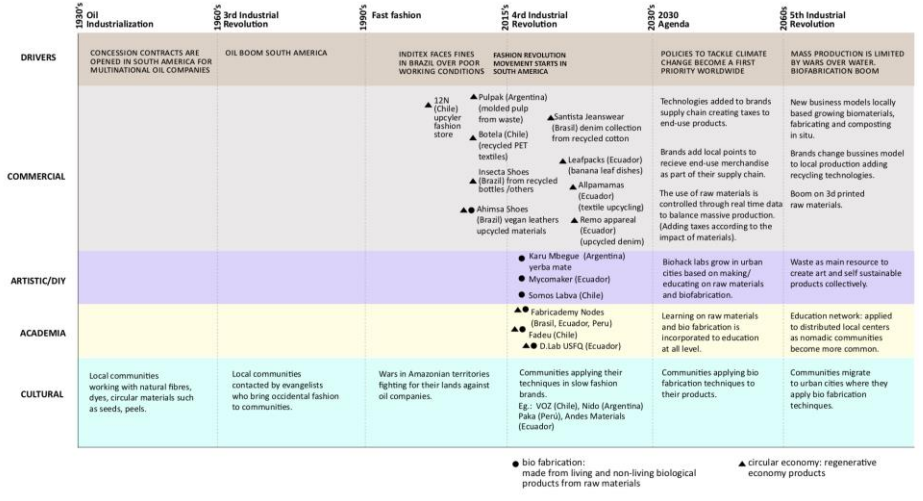

Figure 20. Road Map.

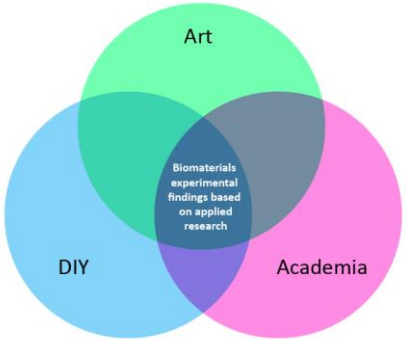

Figure 21. Experimental findings are seen through an interdisciplinary approach. Biohacker spaces, Fab Labs or bio laboratories are DIY labs usually collaborating with different fields of academia. Some are oriented to product development and use art as a medium to present plausible applications; others use biomaterials as a medium to make art.

The zeitgeist from the present is uncertainty about the future. Today's generations feel responsibility to act game changers due to world's climate change. Technology might solve climate emergencies, but there is an urgent need to awake from comfort, to act with awareness as individuals and mostly, to act collectively for a social transformation that drive positive changes forward.

Claudio Alcorso and Post-war Textile Culture

Tracey Sernack-Chee Quee

TAFE NSW Design Centre Enmore, Australia
tsernackchee@gmail.com

Abstract | This investigation of textile entrepreneur Claudio Alcorso (1913-2000) provides new insights into the agency of the Italian design diaspora on global connections in the textile industry of the late twentieth century. The Alcorso family's Jewish ancestry triggered the expropriation of their textile businesses in Rome by the Fascist regime in 1939. Desiring a move far from imminent war, they established Silk & Textile Printers Ltd (STP) in Sydney, producing silk and rayon fabrics using the then cutting-edge technology of screen printing. The business expanded, establishing networks with global textile producers, eventually becoming the largest textile printing operation in the southern hemisphere. The Alcorso's business networks included Carrington & Dewhurst, Courtaulds and Sekers' in Britain, Cohn-Hall-Marx (Cohama) in the USA and Toray and Teijin in Japan. Global connections enabled diffusion of innovative strategies that facilitated development of differentiated products to stimulate consumer demand in the face of increased competition.

KEYWORDS | DESIGN, CULTURE, MANUFACTURING, TEXTILES, GLOBALISATION

1. Introduction

The influence of the European diaspora on art, design and culture in the post-war era has been examined in fields ranging from photography to architecture. However, these investigations have yet to uncover the true extent to which Italian émigrés influenced the global diffusion and democratization of dress and textiles. This paper argues the importance of Italian-born Claudio Alcorso (1913-2000) in the manufacture of artist-designed textiles for fashion and furnishing for Australian and international markets, from 1945 to 1970.

2. The Piperno-Alcorso family in Italy

The Piperno family was well known in Italian textile circles, owning two departments stores and a factory in Rome (Italian Jewish Goods Commission, 2001). Patriarch Amilcare Piperno (1886-1961) served as government comptroller of woollens during World War I, receiving the Knight Commander of the Royal Order of the Crown of Italy in recognition for his service (Draper of Australasia, 1961). Amilcare later diversified his business into fancy silks, opening 'Amilcare Piperno Al Corso' at 172 Corso Umberto I in 1929 (Lupano & Vaccari, 2009). The store specialised in printed silk fabrics, catering to the sartorial needs of the Italian aristocracy, as well as fashionable patricians who had their clothing made to measure. A second store opened at 53 Piazza Fiume in 1937. It was a testament to modernity after extensive renovations by modernist architect Melchiorre Bega (1898-1976), who designed a sinuous interior staircase mimicking the swathes of fabric in the store windows (Università Roma, 2017; Behance Gallery n.d.). The interior featured Bega's sleek, modern timber and glass cabinetry, used to display bolts of fabrics and all the trimmings required to produce the latest fashions for the stores' clients (Villani, 1938).

A catalogue celebrating the second store's opening was designed by another modernist, Futurist artist and aviator Olga Biglieri Scurto (1913-2002), who worked under the pseudonym 'Barbara' (Ministero Per I Bene e Le Attivita Culturali, 2011). The cover showed a map of Rome from the air, marking the locations of Piperno Al Corso as an integral part of the eternal city, alongside historic sites including Hadrian's Column, the Colosseum and the Victor Emmanuel Monument (Piperno Alcorso, 1937). Costume designer and fashion authority Mario Vigolo (n.d.) was retailed to design illustrations interpreting the latest Paris fashions in fabrications sold by the store (Lupano & Vacari, 2009). The business eventually came to define the family, who changed their family name to 'Alcorso' in the 1920s.

Apart from the stores and factory at 24 Via de Campo Marzio, Amilcare had interests in several Roman properties (Camerano, 2004). He held shares in the De Angeli Frua silk mill, and had financial connections to Abraham, Brauchbar et Cie, a Swiss textile business that owned a printing factory in Lyon (National Archives of Australia, 1940-1954). Amilcare's sons Claudio and Orlando had known Vittorio and Bruno Mussolini, the sons of the Italian dictator, since high school. Orlando attended classes with Vittorio, while Claudio had completed his compulsory national service in the Italian air force with Bruno (National Archives of Australia, 1940-1954). It was the Mussolini family that warned the Alcorsos of

their denouncement as Jewish descendants, and the imminent confiscation of their businesses (Alcorso C., 2016). The Alcorsos quickly began liquidating whatever assets they could to raise funds for their escape from Italy.

It was one of Amilcare's contacts, a manager at Abraham & Brauchbar in Zurich who introduced him to Alfred Gugenheim of St Gall, a provedore who smuggled the equivalent of £60,000 across the border into Switzerland in his fruit trucks (National Archives of Australia, 1940-1954). Claudio had driven to London earlier with his father's assistant Paolo Sonnino, ostensibly to take a course at the London School of Economics. Orlando, who was studying languages in Switzerland, was soon joined by his parents, who brought other valuables that they soon liquidated, lodging their escape funds in a Swiss bank account (National Archives of Australia, 1940-1954). After fleeing from Italy, the family's business interests were overseen by a Mr Storoni, a possible member of "Society Tacoel", a consortium of former employees, who bought the businesses after their expropriation buy the Fascists (National Archives of Australia, 1940-1954; Italian Jewish Goods Commission, 2001).

The Alcorso family reunited in London, and began investigating options to establish a business as far away as possible from the coming European conflict. After researching opportunities in several countries, they decided on Australia. Their research revealed that it had the highest per-capita consumption of printed fabrics and few textile printing factories. The family decided that it would be the perfect location for a screen-printing factory producing silk and rayon dress materials (Alcorso C., The Wind You Say, 1993).

3. Silk & Textile Printers (STP) Australia

Arriving in Sydney in early 1939, Claudio, Orlando and Paolo Sonnino established a textile agency they called FISMA (France, Italian, Swiss, Manufacturers, Australia) using sample swatches they had brought from European print houses. Australian department stores, draperies and fashion manufacturers welcomed the Italians, who brought sophisticated designs that added variety to the ranges of more conventional prints that they bought through their British suppliers (Alcorso C., The Wind You Say, 1993).

Gilkes Brothers & Hoskins Ltd were the only Sydney-based producer of screen-printed fabrics at the time (Lech, 2005). The market depended on imported prints, mostly from Britain. Cheaper prints came from Japan, and were relatively inexpensive due to a low exchange rate (The Textile Journal of Australia, 1934). The indent orders brokered through FISMA helped the family to establish client relationships and assess local taste and buying patterns whilst they built their printing factory. By early 1940, Silk & Textile Printers Ltd (STP) was operational, staffed by technicians and designers trained at East Sydney Technical College, who were ready to develop original textile designs along similar lines to FISMA's European best-sellers (Alcorso C., The Wind You Say, 1993).

However, World War II interrupted the Alcorso's plans. Claudio and Orlando's friendship with the Mussolinis became known first to the Australian press and then to the military authorities, who arrested and interned them and Paolo Sonnino as enemy aliens in early 1940 (Alcorso C., The Wind You Say, 1993). Amilcare Alcorso and his wife Delia had by then

embarked on a ship bound for New York. Their Australian re-entry visas were revoked, and despite lobbying the Australian government, they found themselves stranded in New York. Amilcare set up an office in the Rockefeller Center, managing his Australian business through correspondence with Eric Hearnshaw, an accountant employed at STP (National Archives of Australia, 1940-1954).

Production at STP was co-opted by the Australian military authorities to print camouflage fabrics for the war effort, but there was some printing of fashion and furnishing fabrics on a restricted range of base cloths. Three young women artists employed in the design studio – Avis Higgs (1918-2016), Mary Curtis (n.d.) and Betty Skowronski (n.d.), managed the design of fashion fabrics, producing a series of monotone prints that sold quickly to retailers and manufacturers eager to obtain any stock due to wartime shortages. Higgs, Curtis and Skowronski engaged with the local artistic community, taking lessons from Hungarian émigré artist Desiderius Orban (1884-1986). Higgs joined the NSW Society of Artists, led by publisher and artist Sydney Ure Smith, exhibiting in their annual exhibitions. Hearnshaw saw the positive impact of Orban's art lessons on STP's output, agreeing that he could provide art lessons for the entire design team (Lloyd-Jenkins, 2000).

Herbert Read's *Art and Industry* was a major influence on manufacturing at the time. Read's position was that artists were well placed to provide integrated design solutions for industrial purposes, rather than applying pattern to utilitarian products as an afterthought (Read, 1966). His ideas were readily adopted at STP, who launched their collections from 1943 to 1946 under the title 'Art in Industry'. Fabrics were exhibited next to the original artwork for each design, at major hotels and art galleries in Sydney and Melbourne. Product launches attracted glowing editorials in newspapers and women's magazines, often illustrated with photographs of the attractive Higgs, Curtis and Skowronski standing next to their designs (Lloyd-Jenkins, 2000).

Claudio and Paolo Sonnino were finally released from internment when Italy surrendered to the Allies in 1943. Paolo immediately joined the Air Force, whilst Claudio took some time to recover from his internment with Nazis and Fascists whose politics he abhorred. Orlando, whose friendship with the Mussolinis was closer, was not released until sometime later. Hearnshaw continued to operate STP on a day to day basis, reporting frequently to Amilcare in New York. He also acted as Amilcare's agent, brokering the purchase of textiles by Australian wholesalers on behalf of the General Overseas Corporation (Textile Division), the American company with which Amilcare was now affiliated (National Archives of Australia, 1940-1954).

4. Modernage

By 1944 Claudio Alcorso was back at STP as Managing Director, and business was brisk. He endorsed the design direction initiated by his designers and the art lessons delivered by Orban. The Australian government had released stocks of Italian rayon fabrics impounded at the beginning of the war, providing badly needed materials for fashion prints. STP developed a new shrink-resistant, fine wool fabric that they called "Peau d'Ange" (Angel's Skin), with a

view to establishing an export market for printed Australian woollens (Lloyd-Jenkins 2001). The designers created striking prints illustrating the potential of the new cloth to buyers in the USA, South Africa and India (National Archives of Australia, 1940-1954).

The family received good news in May 1945 from Mr Storoni in Italy, advising that ownership of Piperno Al Corso had been restored (National Archives of Australia, 1940-1954). Though little evidence remains about their post-war operations, it is likely that the stores remained under family control. Both were still trading under the Piperno Al Corso name during the Autumn-Winter 1949-50 season, and Amilcare and other members of the Alcorso family travelled often to Italy after the war (Piperno Alcorso, 1949; The Mercury, 1952). Meanwhile, Claudio and Orlando continued to manage STP with support from Paolo Sonnino and Eric Hearnshaw.

In the early post-war period a number of textile producers including Ascher in London and Wesley Simpson in the USA began producing collections of textile prints designed by prominent visual artists (Rayner et al, 2012). In March 1946 costume designer Matilda Etches (1898-1974) brought a collection of Ascher textile prints by artists including Cecil Beaton (1904-1980), Feliks Topolski (1907-1989) and Henry Moore (1898-1986) to Australia to great public acclaim. This direct manifestation of Read's thesis on the importance of art in industry inspired Alcorso to commission his first collection of prints designed by prominent Australian painters.

Alcorso approached Sydney Ure Smith to provide introductions to the members of the NSW Society of Artists. Many eagerly agreed to provide designs. Alcorso provided no design brief, preferring that artists draw from their own artistic idiom – original designs could easily be adapted into repeats by STP's technical staff. Rather than buying the designs outright as was the norm, Alcorso offered a royalty of 2 shillings for every yard sold, a potential future revenue stream that proved attractive. STP tested a limited number of the artist's designs in their 1946 'Art in Industry' collection. Designs by Russell Drysdale (1912-1981), William Dobell (1899-1970), Margaret Preston (1875-1963), James Gleeson (1915-2008) and Donald Friend (1915-1989) were shown to an enthusiastic trade and public audience at exhibitions opening at the Hotel Australia in Sydney and the Sedon Galleries in Melbourne in September 1946 (Museum of Applied Arts & Sciences, 2000).

Figure 1: Russell Drysdale for STP, "Stone and Wood" 1947, screen-printed cotton. Approx. 99 x 95cm, Author's Photograph, National Gallery of Victoria, Melbourne, December 2018.

Department store David Jones, owned by Charles Lloyd-Jones, an amateur painter and member of the NSW Society of Artists, bought heavily from the collection, which was expanded in 1947 and given the title 'Modernage'. Modernage comprised of 46 prints by Australian artists and the design team at STP. As part of a desire to create a national design style, some artists misguidedly translated Aboriginal motifs for their designs, ignorant of their symbolism and of the distress that their cultural appropriation caused to First Nation artists. At the time, Aboriginal people did not hold citizenship, and were regarded as 'protected species', not unlike Australia's distinctive flora and fauna – a resource to be exploited for commercial gain.

Modernage was heavily promoted in women's magazines and the metropolitan and regional press. In June 1947 the Australian Trade Commission launched a textile exhibition including Modernage at the Australian Trade Display Centre in the Rockefeller Center, New York. "Peau d'Ange" woollens were well received, with the fashion writer of the New York Herald Tribune devoting half her column to praise for the sheer, woollen fabric (The Textile Journal of Australia, 1948). Modernage was also used to promote modern Australian design on ocean liners travelling between Britain and Australia. The RMS Orcades and RMS Orontes, built by the Orient Line in 1947 and 1948 respectively, incorporated several Modernage

designs in decorating schemes designed by New Zealand architect Brian O'Rorke. One of these was "Pearl Divers", (Figure 2) designed by Donald Friend (The Textile Journal of Australia, 1949).

Figure 2: Donald Friend for STP, "Pearl Divers", 1947, Screen-printed cotton. Approx. 96 x 89cm. Author's photograph, National Gallery of Victoria, Melbourne, September 2012.

Alcorso positioned Modernage at the top end of the market. A premium price was charged in line with its association with fine art, and high consumer demand due to post-war textile shortages (The Draper of Australasia, 1947). 36-inch-wide cottons were priced at 17/4 shillings per yard, whilst competitor's fabrics were priced at 13/8 per yard for 48-inch width (The Australian Home Beautiful, 1947). Whilst the collection was supported by glowing editorial and advertising, sales were only moderate, and there were few repeat orders. Alcorso believed that the modernist designs may have been too visually challenging for most Australian consumers (Alcorso C., The Wind You Say, 1993). The best-selling design was "Foliage" by Adrian Feint (Figure 3), a traditional design that presaged STP's subsequent return to more commercial floral prints. It was felt that the majority of Australians were not culturally equipped to comprehend modernist design. As Bourdieu (1999) observed, art appreciation and perception involves a "deciphering operation" that is dependent on the viewer's own understanding of aesthetics. This deciphering may not result in appreciation when…"one unconsciously applies the code which is good….for the deciphering of familiar objects to works in a foreign tradition". A mainstream consumer with little aesthetic training or exposure to modernist design might find designs like Drysdale's "Stone and Wood" (Figure 1) somewhat more challenging than a conventional floral. However, it is clear that overly optimistic expectations, combined with high prices and a limited range of narrow

width base-cloths also had a negative impact on sales.

Figure 3: Adrian Feint for STP, "Foliage" 1947, screen-printed cotton, approx. 52 x 90cm. Author's Photograph, National Gallery of Victoria, Melbourne, September 2012.

A positive outcome of Modernage was that it demonstrated STP's capability as textile printers. The factory was soon unable to keep up with orders, and new locations were sought to expand their production base. STP were offered a newly built, former munitions factory in Derwent Park, Tasmania, together with loans, concessions and incentives to relocate their business. Over the next two years STP relocated their entire printing operations from Sydney to Hobart. During the move, all of the screens and artwork for the Modernage collection were lost (Alcorso C., The Wind You Say, 1993).

5. The Leroy-Alcorso Signature Print textile competition

By 1951, STP had diversified into spinning and weaving in addition to printing around four million yards of textile piece-goods annually (The Textile Journal of Australia, 1951). New investments were made in technology, and the company enjoyed nearly a decade of continuous profits. Alcorso secured a loyal workforce from the suburbs surrounding Derwent Park, as well as skilled migrants arriving from the United Kingdom and Italy. He commissioned Australian architect Roy Grounds (1905-1981) to design purpose-built, three bedroom houses at the "Alcorso Village" at Moonah for sale to STP's workers through subsidised loans. These incentives, combined with excellent working conditions ensured that sick-days and accidents were minimised, supporting efficient production continuity (Edwards, 1958).

Alcorso had not forgotten the importance of a Australian artists in developing original prints. In 1953, he partnered with a major client, Melbourne fashion manufacturer The House of Leroy in the Leroy-Alcorso Signature Print Textile Design Competition. He hoped the competition would bring international recognition to Australian artists, as winning designs would not only be printed by STP for Australasia, but also licensed by the Cohn-Hall-Mark Company (Cohama) in the United States and the Berne Silk Manufacturing Company in Great Britain. Designers would be paid 2d commission on each yard sold, with a further prize of £100 awarded to the designer of the best-selling design the following year (The Australian Home Beautiful, 1954). Once again, this royalty-based model provided a cost effective way to commission artist-designed textiles without excessive risk to Leroy or STP, also providing artists with a suitable incentive.

Entries were received from over 750 amateur, student and professional artists, including many artists that had designed for Modernage. Douglas Annand (1903-1976), a Modernage veteran, won first prize of £300 for his design of torn pieces of monotone spotted paper set against a brightly coloured background (The Mercury, 1954, p. 5). The Leroy-Alcorso Signature Print competition ran for a second time in 1955. That year, there were two joint winners each receiving £150, both of whom were amateur artists. The reasons behind the competition's demise remain unclear. It may have been the victim of a changed relationship between STP and Leroy, or complexities associated with paying royalties to artists. Changes occurring in international textile markets may also have been a factor. Japan's textile industry was printing high-quality cotton fabrics at prices that could not be matched in Australia. Other Asian nations were also producing printed textiles that were cheaper than Australian equivalents, despite punitive import tariffs imposed by customs (Owen, 2010). In response to this increased competition, STP strengthened its' networks with producers overseas, and concentrated on their strengths – printing silks, rayons and the new, easy care synthetic fabrics that were then then taking the international fashion industry by storm.

6. International networks

Alcorso began a close business relationship with Sekers Silk, the Australian branch of Sir Nicholas ('Miki') Sekers' West Cumberland Silk Mills, founded in Britain in 1938. The Australian branch was managed by Sekers' friends, fellow Hungarian émigrés Andrew and Vera Kaldor, who arrived in Australia in 1952. Sekers' European ranges had found their way into the Paris collections of Christian Dior, Elsa Schiaparelli, the House of Worth and Jean Patou during the early 1950s. He was regarded as a textile innovator, producing synthetic dress textiles as early as 1945, and 48-inch-wide fabrics for fashion when the norm was 36-inches (Coulam, 1953).

Like Alcorso, Sekers recognised the value of artist-designed prints (Sekers Silk, 1959). In 1960 he accompanied a collection of prints designed by Cecil Beaton, Graham Sutherland (1903-1980) and Oliver Messel (1904-1978) that were exhibited in major department stores around Australia (Draper of Australasia, 1960). Miki Sekers also recognised that it was more efficient for an Australian production facility to print fabrics for his customers in the Far East,

Australasia and South Africa, instead of shipping finished cloth from the UK. STP was well equipped to take on contract printing for Sekers and other European and American textile houses. In August 1961, STP and Sekers cemented their alliance with an agreement appointing Sekers as exclusive distributors of printed and plain silk fabrics produced by STP (Clothing News, 1961).

Alcorso developed direct sourcing strategies to ensure the ongoing supply of base-cloths that could not be produced viably by STP. He visited Communist China regularly from 1957, years before diplomatic relations were restored with western nations, securing a direct supply of supply of silk base-cloths for dyeing and printing (Alcorso C., The Wind You Say, 1993). This ensured that Sekers led the market for printed silks in the southern hemisphere. STP's design team produced original designs, which were supplemented by designs bought by Alcorso from the Paris studio of designer Georges Delhomme, and designs from Sekers' UK collections, which were re-coloured for the Australasian market by STP's design team under the direction of Vera Kaldor. Best-selling prints from the southern hemisphere also found their way back into Sekers European collections (Clothing News, 1962).

Andrew and Vera Kaldor's son John began working at STP in 1957 as Alcorso's assistant, after a textile design course under Bauhaus teacher Johannes Itten in Switzerland, followed by an internship with his godfather Miki Sekers. By 1960, John Kaldor was back working at Sekers as a textile stylist (Graham & Kaldor, 2008). In 1962, he created "Sekers' Australian Artists Originals", a collection paying direct homage to Alcorso's Modernage. Designs for cotton furnishing textiles were commissioned from Australian artists including Modernage alumni Drysdale, Gleeson and Friend and other prominent painters including Cedric Flower (1920-2000), Elaine Haxton (1909-1999), Judy Cassab (1920-2015), John Olsen (1928-), John Coburn (1925-2006), Ian Van Wieringen (1943-) and sculptor Clement Meadmore (1929-2005) (Cochrane, 1992). The collection was launched in February 1963 in an exhibition titled "Art in Décor", at Sydney's Dominion Galleries and the Museum of Modern Art (Heide) in Melbourne (Clothing News, 1963). However, the fabrics were printed by Kanebo in Japan rather than by STP in Hobart, highlighting the high quality and low cost of Japanese printed cottons that was making Australian production increasingly unviable (The Australian Home Beautiful, 1963).

Alcorso stepped up STP's export programs in response. In his memoir, he recalled how proud his father Amilcare would have been, had he known that STP sold 200 rolls of printed silks to Galtrucco in Milan, which he regarded as the best fabric shop in Italy (Alcorso C., The Wind You Say, 1993). In 1964, STP participated in the Australian Trade Commission's floating exhibition on the trade ship 'Centaur', which travelled through Asia carrying displays, public relations staff and fashion models, staging events and meetings with buyers at each port of call (Clothing News, 1964). STP's exports to England, Europe, Hong Kong and New Zealand increased from £98,000 in 1961 to £170,000 by the end of the 1963-64 financial year (STP Holdings Ltd, 1964). Alcorso's successful export performance was recognised by the Australian Trade Commission with a number of special export awards (Clothing News, 1964). By 1967, STP had merged with Sekers Australia and their main competitor, Tennyson Textiles of Sydney, forming Universal Textiles (Australia) Ltd (UTA). The merger consolidated and

rationalised production operations, creating a more efficient, integrated supply chain (Universal Textiles (Australia) Ltd, 1967). UTA diversified their products, producing new fabrics for niche markets. 'Contender' sail-cloth was produced for the marine market; special, hard wearing synthetic blends were produced for school uniforms and furnishing products such as readymade curtains were manufactured and pre-packaged for direct sale to retailers (Universal Textiles (Australia) Ltd, 1968).

The company invested in new technologies including sublistatic (heat-transfer) and rotary screen-printing, providing increased production flexibility (Universal Textiles (Australia) Ltd, 1968). The business attracted interest from overseas and a number of prominent international textile companies held significant shareholdings in UTA. Lancashire firm Carrington & Dewhurst held 420,000 shares, as did James Nelson (Australia) Pty Ltd, a wholly owned subsidiary of Courtaulds in the UK. Both the Toyo Rayon Company Ltd (Toray) and Teijin in Japan held 300,000 shares each; Sekers (UK) held approximately 167,000, whilst Bruck Mills (Australia) Ltd, the local subsidiary of the Canadian-based producer held nearly 62,000 shares (Universal Textiles (Australia) Ltd, 1967).

Throughout the 1960s Alcorso continued his patronage of the arts through UTA, together with his like-minded colleague John Kaldor, who now managed design direction and marketing for the company. In 1966 they established the 'Alcorso Sekers Travelling Scholarship Award for Sculpture', providing £1,000 annually to fund overseas travel for an artist (The Sydney Morning Herald, 1965). The competition ran until 1969, receiving many entries from the crème of Australia's sculptors, including Col Jordan (1935-), Michael Kitching (1940-), Robert Parr (1923-), Ken Reinhard (1936-) and George Baldessin (1939-1978) (Art Gallery of NSW, 1967). However, in 1969, its final year, the travelling scholarship was somewhat overshadowed by another of Kaldor's art initiatives.

When it was completed in 1969, 'Wrapped Coast', the installation by Christo and Jeanne-Claude at Little Bay, Sydney, was the largest single artwork in the world. More than one hundred workers, including professional mountain climbers, art teachers and students contributed to the realisation of the artist's vision to package the landscape in textiles. UTA donated the fabric used by Christo to wrap the coastline - it was another of their new specialized products - a durable agricultural grade textile designed to suppress weed growth (Safe, 2013).

7. Sheridan

In 1967 UTA launched printed bed-linen under their existing "Sheridan" brand (Sheridan UK). Based on an international trend exemplified by Cannon and Fieldcrest in the United States, Sheridan produced sheets primarily in bright printed florals. Advertising agency Ogilvy and Mather developed a promotional campaign using endorsement from high-profile Australians including fashion designer Merivale Hemmes, explicitly targeting an emerging market of young fashion followers (Sheridan, 1970). The advertising was sometimes controversial, earning Sheridan and Ogilvy & Mather notoriety as well as publicity. Liberal Party Minister for the Army Andrew Peacock offered to resign his position over the appearance of his

fashionable wife Susan in advertising for Sheridan in late 1970. Susan Peacock had donated her $100 fee to charity, but her endorsement still caused a scandal. Sanity eventually prevailed and Peacock's resignation was rejected (The Canberra Times, 1970).

UTA soon became a prime target for a corporate takeover. It had attracted the interest of Dunlop (Australia) Ltd, who saw an opportunity to add the newly rationalised business to its local textile and apparel operations. The Alcorso family, still major shareholders and directors of UTA, did not oppose the offer – thought that it would be good for the industry and their workers. The takeover was completed in June 1969. Claudio and Paolo Sonnino joined the board of Dunlop, whilst Orlando left the business to pursue other interests (Alcorso C., The Wind You Say, 1993).

It was soon obvious that the Board of Dunlop had little time for art patronage, or any social concerns that characterised Alcorso's management style. They questioned the donation of fabric to Christo. They made it clear that they wanted immediate results from all product lines, and were unsympathetic about the performance of the Sheridan, still a fledgling brand. Alcorso became increasingly disillusioned with the Dunlop's lack of vision, resigning from the Board in 1970 (Alcorso C., The Wind You Say, 1993). He was soon followed by John Kaldor, who set up his eponymous business 'John Kaldor Fabricmaker', shortly thereafter (Safe, 2013).

In the 1980s Sheridan developed an iconic collection of artist-designed bed-linen that finally enabled Alcorso's vision for homes furnished with textiles designed by Australian artists to become a reality. From 1984 Sheridan produced a series of quilt cover sets designed by artists including Jenny Kee (1947-) and Ken Done (1940-). At the time there was international interest in the 'Australiana Pop' aesthetic - kitsch interpretations of Aboriginalia and Australia's unique flora, fauna and tourist attractions including the Sydney Harbour Bridge and Luna Park, incorporated into colourful and often comical graphics. The comparatively lower cost and durability of Sheridan's Australiana bed-linen, with its ability to change a room instantaneously, was an attractive option for mainstream consumers, compared with the limited appeal of Modernage fabrics twenty years earlier.

Sheridan opened a flagship store on Madison Avenue, New York City. Macy's and the Federation Group also stocked the brand, together with major retailers in Asia including Daimaru in Japan. At one time, the company was making bedlinen in 110 different sizes to comply with sizes in multiple overseas markets (Sheridan, 2012). Sheridan continued to honour their founder's goal to unite art with industry. In 2014 they launched the 'Modern Art Series' of artist-designed quilt cover sets with a catalogue including Alcorso's biography (Sheridan, Summer 2014). In 2017, the company revived an internationally successful collaboration with Australian artist Ken Done, who produced a new collection of quilt cover sets similar to those he produced for Sheridan in 1985 (Figure 4).

Figure 4: Printed bedlinen designed by Ken Done for Sheridan 2017. Author's photograph, Westfield Bondi Junction, Sydney, August 2017.

8. Alcorso after Textiles

Claudio Alcorso is not only remembered for his work in textiles, but also for other significant contributions to Australian culture. He helped re-establish wine production in Tasmania by founding the 'Moorilla' winery at his home in Berriedale in 1958, now the site of the Museum of Old and New Art, "MONA" (Alcorso, 1993). From 1970 to 1974, he led the Australian Opera to autonomy (Talia, 2000). As chairman of the Tasmanian Arts Advisory Board, he ensured that heritage buildings at Salamanca in Hobart were saved from demolition. He later initiated a grand vision to restore Hobart's former 'IXL' factory buildings, repurposing them as an international boutique hotel and an arts centre, now part of the University of Tasmania (Alcorso C., The Wind You Say, 1993).

Claudio Alcorso was a champion of Tasmania's pristine environment, writing extensively on the high quality foods, craft furniture and leather goods produced there by artisanal makers. As a prominent member of the Tasmanian environmental movement, he campaigned to prevent the damming of the Gordon Below Franklin River, a landmark victory of the Australian conservation movement. As a migrant, he was a strong supporter of a multicultural Australia, and an advocate of equality for Australia's First Peoples, speaking

often at Aboriginal Land Rights rallies (Alcorso, 1993). He was also an outspoken proponent of the Australian Republican movement, up to his death in 2000.

9. Conclusion

This investigation of the life and business activities of Claudio Alcorso provides new insights into the agency of the Italian design diaspora on global interconnectedness in the textile industry. It demonstrates how migration facilitated the diffusion of innovative business strategies that enabled the development of new, differentiated products to stimulate consumer demand in the face of increased globalization. It has enabled new connections to be made between the production of art, design, culture and textile manufacturing, against the backdrop of late twentieth century globalisation.

Collaborative Capabilities: aural encounters in digital/analogue co-creative making

George S. Jaramillo*[a], Lynne J. Hocking-Mennie[b],

Abstract | Contemporary arts and design practitioners are mobile, diverse and interdisciplinary. Often operating as micro-businesses or solo practitioners, they need new and innovative approaches that promote collaborative knowledge exchange and transdisciplinary experimentation. This ongoing practice-based research covers the developing co-creative relationships that arise through integrating digital making and data-driven processes as inspiration within collaborative distributed networks of design and making. The authors developed an analogue/digital transformation process for sound-inspired pattern creation, initially explored in the context of textile pattern design with a cohort of practitioners geographically distributed across Scotland, and now expanding out across other craft/design disciplines. Through a participatory design approach (Bannon & Ehn 2012), the project developed a series of collaborative workshops where the practitioners worked together with the researchers to develop new processes for inventing and generating transdisciplinary designs using non-traditional approaches, with designs taking inspiration from the "heard" rather than "seen" environment. It uses the robust multi-sensory process to promote alternative environmental attunement to place and landscape, whilst experimenting within a collaborative digital platform. Through these different lines of work, we explore what it means to be a practitioner in the twenty-first century in Scotland and beyond, including challenging the arts/crafts and craft/design divide through collaborative interdisciplinary participation.

KEYWORDS | COLLABORATIVE MAKING, DATA-DRIVEN DESIGN, DISTRIBUTED COLLECTIVES

1. Introduction

In the arts and crafts the notion of the lone genius creator is a common trope. Even in co-located arts collectives, collaboration tends to be limited to teaching, administrative or financial situations to share in the burden of these issues, rather than collaborating in an extended fashion on creative endeavours (Montouri & Purser 1995, Sennett 2009). Yet, this image of the lone creator is a limiting concept for the modern practitioner, particularly in an age when technologies permit collaboration at distance and where even remote geographies are digitally accessible. Modern arts/crafts practitioners are mobile, diverse and interdisciplinary; they expect to access information, skills and knowledge digitally; and they need to compete more and more with larger commercial/industrial enterprises across the same digital and analogue platforms (Bennett 2018). The need for new techniques and acknowledgement of cooperative approaches to design and creation, whether between groups of designer-creators or co-creating designs with other stakeholders are needed and mechanisms that support these new interactions are required.

This article explores the ongoing work and insights of the Royal Society of Edinburgh (RSE)-funded project *Distributed Capacities,* a creative network of contemporary Scottish art and design practitioners through a distributed and disruptive manner of collaboration. It uses a developing and robust digital/analogue multi-sensory process that promotes alternative environmental attunement to place. It does so through the consolidation of a small cohort of textile designer/makers into conversation and practice with a new collective of non-textile practitioners. In doing so, the project aims to explore what it means to be a practitioner in twenty-first century Scotland, including challenging the arts/crafts divide through collaborative interdisciplinary participation. Furthermore, this project questions existing ways of making and collaborating using digital/analogue avenues that augment, but do not replace the influence of the practitioner on the design process. It asks two key questions:

- How can multi-sensory digital/analogue processes influence contemporary Scottish maker/designer relationships?
- In what ways can these relationships develop a different attunement to the contemporary landscape and response to this?

This article will discuss the ongoing reflection, insights and challenges of this aural driven project. It will first provide a brief theoretical context in the provenance of the project alongside three key theoretical ideas of sound attunement, making and co-creation. This is followed by description and analysis of the first two research gatherings alongside participant reflections between those gatherings. Furthermore, we add a short component of ongoing work from the third digital gathering just before the onset of the pandemic. We finish with a developing critique of the work and a set of next steps for this project, which opens up dialogues of participatory design, collaborative making and a newly found perspective in sensory and place promoted within a twenty-first century Scottish context and through encouraging conversations between practitioners from different disciplines.

2. Context

This project builds upon the existing body of research and practice that took place with textile practitioners during a year-long research project called Aural Textiles, which explored the inputs of non-visual stimuli into textile production (Authors 2019). The bespoke sound-to-pattern process, developed through the project, involved listening and recording landscape sounds and transforming those sounds into textile patterns and designs. We evidenced that a novel set of contemporary textile patterns, across a range of textile disciplines, can be generated in response to the aural environment. Three key insights came out of that initial project:

1. Data-driven processes augmented but did not replace the role of the designer/maker. Each practitioner exerted control over the output that was generated that was dependent on (a) their pre-existing skill set and (b) engagement with the other project participants.
2. A digital/analogue approach to working enabled practitioners to experiment with their process and technique, and the novelty of a data-driven design approach enabled them to be creative in new ways.
3. The use of digital platforms and ease of open source ways of processing and moving information allowed for the practitioners to share sounds between each other, as well as ask and answer questions or provide reflections on their own working practice within a private forum.

Therefore, the impact has been not only new entanglements between practitioner and their landscape and with each other, but an overall democratisation of the design and creation process. It is these new entanglements that this *Distributed Capabilities* project builds upon through a proposed design collective that promotes distributed and disruptive collaboration, including and extending beyond the original cohort of textile practitioners. Before moving towards the gathering, we briefly explore the three key theories that ground our research.

Sound Attunement

The sense of hearing is a key component of living things. In humans, the sense of hearing comes from the interaction between small air vibrations received within our ears and transmitted to auditory areas of the brain. This ‘sonorous presence’ (Nancy 2007) is always around, present in the landscapes and places humans inhabit. Listening or sound attunement ‘makes us re-think our relation to power and in deep listening a deeper dialogue is understood’ (Back 2003: 274). This is further emphasized in the way that sound is ‘tendentially methexic’ (Nancy 2007:10) meaning that sound and the act of listening has a sense of sharing and participation, beyond what is viewed and seen (Johnson 2016). On the other hand, listening also becomes a ‘decentred, receptive state’ (Williams 2019: 648) allowing for a multiplicity of sounds to inform how we understand the world around us. Listening, therefore, is more than just one type of state and thus should be a nuanced practice engaging the maker of sound (e.g. human, animal, or a thing, like the siren sound, or

the low hum of electricity) and the practice of receiving that sound, allowing time to move beyond immediate interpretation. Attuning to the sonorous landscape is important not only to challenge our visual bias, but to open new inspirational cues in creative practice.
The sound-to-pattern process (Mennie & Jaramillo 2018) used in this project promotes this sound attunement by allowing participants the ability to not only pay attention to the sounds around them, but to use and manipulate them into a malleable intermediate and give physical form to the concept of sounds, enabling tangible interactions with them (Figure 1). These intermediates began as spectrograms but have, in the course of this project, taken the shape of a variety of emotional or haptic interpretations of sounds.

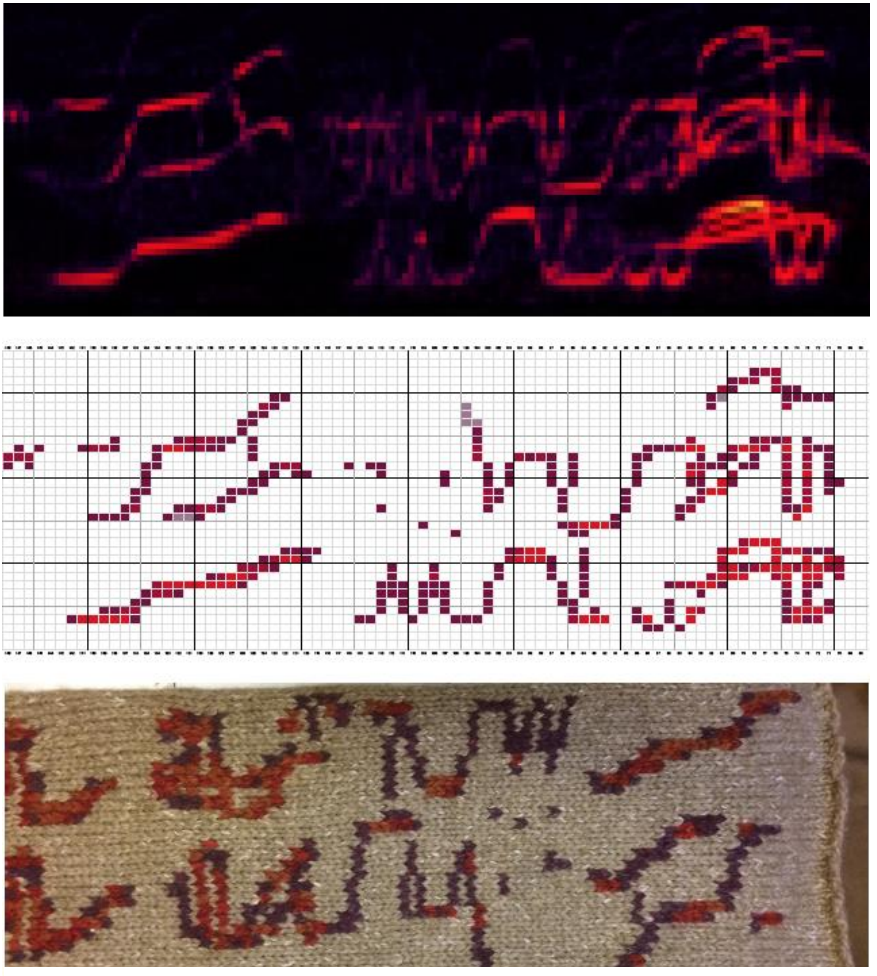

Figure 1: The initial process showing the phases of capturing, transforming and visualising the lapwing bird sound into pattern and test weave/knit. (Source: Authors 2018)

Hybrid ways of making

The requirements for new approaches of making continue to grow as our design and product understanding evolve beyond industrial processes. These industrial processes can be seen as the instigators of the division and separation of the fine arts and applied arts. Digital practices are beginning to show that these divisions need not be made and that links between artistry, designing and creating are possible through what is termed a hybrid way of making (O'Donovan et. al 2017). In our existing work this analogue-digital-analogue iteration allows for an experimental and easily prototyped approach to making. This idea parallels work of Andrew & Diamond (2018) that sees a broadening acceptance of digital tools into textile craft. In this sense, the collaboration happens not just between people but between people and the digital process thereby mutually augmenting each other. It is this mutual augmentation that we will explore in our network, extending into disciplines beyond textiles by inviting each textile practitioner to pair up with a practitioner from another discipline in order to disseminate and further explore the process of data-driven design.

Co-creation

The idea of building and designing together traditionally involved sharing skills, responsibilities and forms. As industrial procedures forced the separation of design from production and from consumption the notion of creating things together was relinquished to the designer and maker. Yet, from the 1950s onward the idea that people, user, participants, or stakeholders all could have a say into the design and decision-making processes was exemplified through participatory design (Sanders and Stappers 2008), user-centred design and the notion of co-creation. Co-creation describes a process of producing items of mutual value, allowing design and production to sit between multiple stakeholders and creator (Prahalad and Ramaswamy 2004). This, however, only answers a part of the evolving idea of co-creation where it is seen mainly as a connection between a creator and a group of users or consumers. The work of Ramaswamy and Ozcan (2018) further this discussion towards an interagencial socio-material assemblage of co-creation. Their value-in-interactional creation supports the agency between multiple actors within a collective of making. For the purpose of this project, we support the notion of co-creation 'as a creative process that taps into the collective potential of groups to generate insights and innovation' (Rill & Hämäläinen 2018: 24). This allows an understanding of thinking that is not only inclusive of the value making approach but also incorporating the multiple agencies inherent in this collaborative project. In the end, these three components of hybrid making, co-creation and sound attunement form the foundations of the ongoing research enabling a rich and strong area from which to develop the work.

3. Process

The six previous Aural Textiles participants, whose practices encompassed weaving, knitting and screen printing, enrolled in the Distributed Capabilities project. Six new creative practitioners were recruited to take part in the project, with disciplines spanning fashion, jewellery, ceramics and woodworking. The project was planned to take place over three phases spanning the course of 18 months: exploration, iteration, and curation. Each phase would allow the participants' time to work with each other at a relatively longer pace, punctuated with three weekend gatherings, and culminating in a public exhibition. The gatherings use a participatory and design innovation methodology (Bannon & Ehn 2012; Dixon & Murphy 2017) that addresses complex challenges through new design practices and bespoke participant engagement. Through our creative and participatory design labs we collaborate with practitioners, addressing the research through creative approaches to co-create preferable futures. We brought this expertise to ensure an interactive session leading to positive and productive outcomes. Key areas for exploration included: engagement, partnerships, governance structures, as well as evidencing value and impact. In-between these gatherings, a digital platform enables continued support, knowledge exchange and reflection, maintaining momentum and presence whilst in a distributed manner.

Figure 2: The first gathering showing the collective group of participants (Source: Sambo 2019)

Gathering 1: Huntly

The first gathering in April 2019 allowed project participants to meet each other and share details of their respective practices. It also allowed researchers to share an overview of the sound-to-pattern process as a starting point for more detailed explorations between pairs of practitioners, as well as, allowing researcher to partake as participant (Chapman 2018). By the end of this gathering, the participants formed pairs comprising one member of the previous Aural Textiles group and one of the new practitioners, with some participants entering into more than one pairing. The intention for such pairings was to understand how insights gained by participants in the previous Aural Textiles project would be shared with the new group members (Figure 2). In the four months after this first gathering, each pair met in person and virtually a number of times to further explore their ideas and processes for sound-inspired collaborative creation of objects across their respective disciplines.

The gatherings were documented in our online blog and Instagram page as a way for all participants to share progress and thoughts with each other. Recorded interviews were conducted with all participants in order to establish each practitioner's prior experience of data- or sound-inspired design and collaborative working; current working models (i.e. distribution of commercial work (retail, wholesale), research & development, residencies, exhibitions, teaching, other sources of income) and anticipated impacts of the project on their practice. Opportunities for future commercialisation were also discussed. The majority of participants indicated that they wanted the project to provide them an opportunity for creative exploration without a commercial focus, to "foster their artistry" (Wilckens 2019) but were interested to explore how outputs might be commercialised in the future. There was also a consensus among the practitioners that they wanted to challenge some of the expectations around "craft" – what it is; how we can use it to communicate and challenge ideas around identity in present-day Scotland; and how we value "making" (as individuals, groups, society).

After the initial meeting, the original members and the new participants paired up and agreed to meet for a six-month exploration phase, which they documented in reflective blog posts and on their business Instagram accounts. During this period, the pairs (and evolving trios) explored the connections between their distinctive disciplines, including between jewellery making and weaving and the connections of ceramics and surface printing. One collaboration in particular began to push the boundaries of sound exploration. As expressed in a blog post:

> "One theme that we plan to develop is the idea of silence. Standing on the open moorland, Lewis stretches out as low rolling hills. Beyond that is a huge open expanse of sea and horizon. Apart from the roaring wind in your ears, the island is both visually and aurally quite quiet. Even the wind seems to turn to white noise after a while. This idea of silence relates back to the spectrograms – we'll be looking at the negative space in the spectrograms – the background noise or silence as inspiration." (Stevens 2019)

Figure 3: A screenprinting skills sharing session experimenting with the use of plastic knit pattern sheets showcasing the final output (Source: Sambo 2019)

This brief description of a collaborative weekend between two of the practitioners evidences a new way of perceiving the wind. Rather than the sonorous presence it is the 'sonorous absence' or the negative capabilities of sound become the inspiration for further investigation. The gaps in-between the sounds form a new type of attunement to what is active in the landscape. These types of encounters carry on towards the second gathering in September 2019.

Gathering 2: Helmsdale

At the second gathering, participants brought materials and tools for hands-on sharing and creative experimentation; as well as samples of work created during the exploration phase. A group reflection on sound-inspired design and collaborative working practices also took place, as well as individual interviews with each participant. Participants were tasked to share with the rest of the group a particular component of their practice. This was done to support creative exchanges but also to consider how public engagement activities could be created and worked out. This developed into a series of ad hoc creative encounters (Figures 3 & 4), with practitioners all learning and experimenting from different creative practices and understanding the processes of each practitioners' way of making: when handing tools and objects from one practice over to an individual from another, the participants were less constrained by technical boundaries or commercial viability. This certainly fed the experimentation in the room and delivered some practice-led surprises. "I had never

thought to do it that way before" was a common remark. (Prosser 2019). It also laid the foundation for our next gathering looking at how we can best enable people to share with each other this sound-to-making process.

Figure 4: Outputs from the tile making session . (Source: Sambo 2019)

Interestingly, some of the practitioners are starting to move away from the data-visualisation elements of sound inspiration and have started exploring their emotional and graphic responses directly to the sounds; while others have started to introduce additional datasets into their designs. Both approaches point to a more in-depth and multi-layered engagement by the practitioners with the soundscape. At the end of the gathering, there was further discussion around potential routes/opportunities to commercialise outcomes from this project. At this stage, it was felt that this distracted from the main aims of the project and negatively impacted the participants' experiences of the project, and the researchers decided not to pursue this further with the group until after the project was completed. Also emerging from this gathering was a clear sense that many participants desire greater input into the direction of the project in terms of defining the research questions and devising ways to address these, suggesting that over the extended period of this project the practitioners have shifted their perceptions of themselves from "practitioners" to "practitioner researchers".

Gathering Three: Digital Gathering

The plans for a third gathering in March 2020 had initially been planned for a public engagement weekend at the UNESCO World Heritage site of New Lanark in south-central Scotland. Participants would have shared and critiqued their ideas of collaborative work and finalised their plans for creating objects for what was then an exhibition in autumn 2020. This, however, was not to be the case. The COVID-19 pandemic caused a massive halt to everyone's lives and with it the project. This gathering though marked a period of rethinking and reworking and a point to pause upon the work up to the beginning of the lockdown. One of the collaborative pairs began to express their work not through the sound but rather

Figure 5: Initial collaborative output between weaver and jewelry maker (Source: Booker & Stewart 2020)

through their own technical process (Figure 5). Through their online and in-person discussions they chose to find 'a common vocabulary to make together, where our practices can meet—that had to come first' (Prosser 2020). Another collaborative pair has shown a developing connecting between knitting and ceramics. Inspired by aspects of memory, dance and movement the knitting incorporates dropped-stitches and other 'imperfections' to attune to ideas of dementia and memory loss. These knitted fabrics are then used to make impressions into clay and fired. This creates two unique interactions, the first is the loss of the fabric, and the second the permanence of the stiches embedded into the finished glazed piece (Figure 6). This has brought about what one of the participants states as 'playing at the edge of what the materials can do conceptually' (Prosser 2020). The fusion of knitted fabric and vitreous nature of ceramics create a new and exciting hybrid connection.

Figure 6: The experimental artefacts between the knitted fabric and the clay imprints (Source: Hopcroft and Sinclair 2020)

As with any type of research involving people, inter and intra-personal challenges arise within the collective. In particular as the collective has grown the necessity for ongoing reinforcement is needed from the researchers. The use of various social platforms allows the necessity for collective sharing, though does not maintain a strong level of connection if it is not continuously used or updated. This and other challenges are ongoing and will require further investigation and review towards the end of the project. Alongside these developing insights are ongoing reflections by the practitioners whose developing understanding of sound attunement has expanded form the initial research space. One participant states, regarding her exploration of call and response to dances and songs, 'I'm fascinated by the

idea that sound doesn't just originate from the performer, and that an active audience contribution becomes a vital element in the overall musical experience' (Hopcroft 2020). This notion that sound is decentralized from the soundmaker reflects back upon the earlier aspects of listening, taking into account that sound making and listening require multiple way of interacting and interpreting.

4. Next Steps

This article has explored the varying stages of an ongoing design research project. It focuses on the collaborative developments of cross-disciplinary and sound-inspired making between a group of practitioners across a distributed network in Scotland. Since March 2019, this collective has encountered new approaches to aurally engaging place as well as working through a growing collective. Its needs and challenges have provided much needed discussion around the tools used, and the needs and desires of the making community.

It has also provided a small window into the developing work to a point at which the COVID pandemic would impact the wider creative community. The next stages of this project will look towards consolidating the collective work, working through pandemic related issues of collaboration, and moving towards curation of the co-created objects in the Spring 2021 for a final exhibition. It is hoped that we will deliver public workshops on sound-inspired design/making as a way to develop the understanding of and storytelling around sound-inspired making and objects. In the end, this project has undergone a series of key transformations from small collaborative network focused around textiles to an evolving assemblage of practitioners. It has opened up dialogues between making and listening, providing the practitioners with new tools not only for their own practice but new ways of working (together).

Abstract | The integration of ICT, open source software and practices, digital fabrication and online marketplaces has enabled designers, engineers, and makers to independently design, distribute and manufacture the physical replication of tangible Open Hardware and Open Design artifacts. Orchestrating these distributed chains, actors and technologies requires comprehensive documentation of elements and across multiple domains and applications. The goal of this paper is to explore how an ontology of Open Hardware and Open Design artifacts could be collaboratively designed and what could be its main elements. In this paper, we present the results from a workshop that explored the prioritisation of domain concepts through a game of card sorting/generation to classify the elements of an ontology. Furthermore, we elaborate insights and Research through Design strategies towards integrating the design of ontologies with the participation of users and their communities, bringing Community-Centred Design to ontology engineering as both Meta-Design and Ontological Design.

KEYWORDS | OPEN DESIGN, OPEN HARDWARE, ONTOLOGY, DOCUMENTATION, META-DESIGN

1. Introduction

The integration of ICT, open source software and practices, digital fabrication and online marketplaces has enabled designers, engineers and makers to independently design, distribute and manufacture the physical replication of tangible artifacts. This possibility has been reinforced with the increasing ease of organising both local and global supply chains connecting local manufacturers, manufacturers in China and the distributed network of makerspaces. These elements constitute the Open Hardware (Ackerman, 2009; Gibb, 2014) and Open Design phenomenon (Abel et al., 2011; Bakırlıoğlu & Kohtala, 2019; Cruickshank, 2014). This generates innumerable possibilities for design in practice, education, research, entrepreneurship and social innovation. Orchestrating these chains, actors and technologies can be a complex task, since its distributed nature renders even the discoverability of such documentation a critical issue. Distributing and sharing design projects over ad-hoc value chains requires a comprehensive documentation of elements beyond the mere tangibility of artifacts (processes, software, electronic design, …) spanning across multiple domains and applications.

There is a gap in practice and research regarding how such documentation can be generated and managed, given its complexity in terms of elements (CAD files, video, images, code, schematics, bill of materials, ...) and technical and application-specific information (authorship, copyright, information architecture, code, patentability, function, application, ...) adopting different documentation formats and practices (Lena-Acebo & García-Ruiz, 2018; Menichinelli, 2018; Milara et al., 2019). The goal of this research is to fill this gap by exploring how an ontology of Open Hardware and Open Design could be collaboratively designed. In information and computer science, an ontology is the semantic level of abstraction of data models in a database: a formal representation that model a domain of knowledge or discourse designed as a digital artifact with specific purposes; it informs data structures and interfaces in digital environments, tools and platforms (Gruber, 1995, 2009). Therefore, in the context of this article we focus on ontologies as formal description of data formats for documenting Open Hardware and Open Design projects. Here the ontology by itself is not a complete system ready to be used, but a first prototype of a set of metadata that enables developers to build and integrate systems on top of it, in order to aggregate data from multiple platforms and sources that would be thus standardised and easily catalogued and discovered by users.

The main research question of this paper is: What could be the main entities of an ontology that describes Open Hardware and Open Design projects? The topic was assessed through a card sorting game workshop in which participants classified and prioritised the elements of an ontology, considering its domain concepts. This paper elaborates such experience by proposing some contributions about how the design of an ontology can be co-created, and ultimately also on how the design of design ontologies can be reconfigured as both Meta-Design and Ontological Design. By reflecting upon the results and limitations of the workshop, three Research through Design strategies are developed for three platforms in

order to integrate the practice and research of the design of ontologies with users and their communities' participation towards a Community-Centred Design to ontology engineering.

The paper is organised in the following structure: this introduction (1) sets the context, goals, research questions and methods of the article. The next section (2) clarifies the relationships between the design of ontologies, ontologies of design and Ontological Design. The workshop and its results are then documented (3), and insights from them are discussed (4). The last section (5) summarises the main results and suggests approaches for overcoming the limitations of this research.

2. Ontologies and Design

The representation of artifacts and the processes for creating them has always been a central element of the design activity (Diaz-Kommonen, 2002); this is even more important with open projects, that are shared, collaboratively edited and enacted in a distributed way. Sharing the documentation necessary for the design and creation of artifacts is a key element: for this reason, the concept of access to the (open) source of a design has become the most popular approach to designing with and for open and peer-to-peer distributed systems (Menichinelli, 2016). This paper focuses on one specific foundational element of design representations: ontologies. The development of ontologies is a key aspect in developing the organisation of the information describing design artifacts and processes (Menichinelli, 2018; Svenonius, 2000).

Ontologies, however, cannot be considered only as the structure of the data for design artifacts and processes: the connections between design and ontologies are more profound. The concept of ontology has here a duality: "In philosophy, ontology is the study of the nature of reality and the categories of things that exist. In information science, an ontology is a formal representation of the universe of things that exist in a specific domain. What these two approaches to ontology share in common is that they both articulate a universe of entities and relationships between entities" (Pomerantz, 2015, pp. 46–47). Following this, the connections between design and ontology take place on at least three directions: 1) design of ontologies (ontology as a design material); 2) ontologies of design (design artifacts and processes described by an ontology); 3) Ontological Design (ontology as a worldview which is designed and which designs) (Menichinelli, 2020).

In design of ontologies (1), the adopted meaning of ontology is the one from information science and computer science. The role of ontologies is to enable the sharing, reuse and analysis of common understanding of the structure of information among people or software agents (Noy & McGuinness, 2001). Ontologies are also designed with a purpose: "formal ontologies are designed artifacts, formulated for specific purposes and evaluated against objective design criteria" (Gruber, 1995, p. 907). They are shared among agents and sustain their agency: "an ontology is a description (like a formal specification of a program) of the concepts and relationships that can exist for an agent or a community of agents" and

"a specification used for making ontological commitments" (Gruber, 1992) by defining "the vocabulary with which queries and assertions are exchanged among agents" (Gruber, 1995, p. 909). In a database, an ontology is the semantic level of abstraction of data models, and enables the integration of heterogeneous data sources, enabling interoperability and specifying interfaces (Gruber, 2009).

Design practice and artifacts can be considered and therefore documented in several different ways (Menichinelli, 2018): design as (a) a process ("i.e. step by step instructions"); (b) as an organisation ("i.e. networks of interactions, work organisation"); (c) a documentation ("i.e. blueprints"); (d) as a production ("i.e. files ready for direct fabrication"); (e) as an artifact ("the artifact and its description"). In the direction of ontologies of design (2), designers adopt a Meta-Design perspective self-reflexively elaborating ontologies that describe all these aspects of the design practice, from processes (Green et al., 2014; Menichinelli, 2018) to design engineering activities (Sim & Duffy, 2003). For example, practitioners and researchers have proposed ontologies of open projects in Fab Labs (Määttä & Troxler, 2011; Troxler & Zijp, 2013). Other researchers proposed that, more generally, the role of designers in Open Design is to become meta-designers by being database and interface designers that create multidimensional design spaces based on a database ontology in order to enable users to become co-designers (de Mul, 2016).

Designing an ontology is a way of characterising the world and its entities through language by creating a classification system and vocabulary that provides the conditions for collaborative activities to emerge (Diaz-Kommonen, 2002; Svenonius, 2000). This leads to the third direction: in Ontological Design (3) the adopted meaning is from philosophy and about the human condition. Ontological Design "stems from a seemingly simple observation: that in designing tools (objects, structures, policies, expert systems, discourses, even narratives) we are creating ways of being. that we design our world, and our world designs us back— in short, design designs." (Escobar, 2018, p. 4). Designing is fundamental to being human, and in turn we are designed by our designing, and in this aspect Ontological Design mainly works on the philosophical level of Meta-Design. And more broadly, with a conscious Ontological Designing we design not just artifacts but rather a new way of being, since they embed culturally specific intentions (functions) and therefore participate in agency. As a practice, Ontological Design can bring social change because by showing the possibility of multiple and complex worldviews not just for the design of artifacts, but also of material and immaterial infrastructure (management systems, communication systems, …) and systems of thought (Willis, 2006).

3. A workshop for collaboratively designing an Open Hardware and Design ontology

3.1. Goals and structure of the workshop

The inherent openness of Open Hardware and Open Design projects and the often DIY and empowering nature of the practices and principles of the Maker Movement give place to the centrality of how users interpret project documentation. The access to the documentation, infrastructure, and tools that enable potentially anybody to edit projects, also increase the amount of modifications, forking, duplicates and so on. If not well structured, project documentation can easily give way to misinterpretations and deviations from the intentions posed by the original or previous authors, creating the danger of an increasing degree of redundancy. This complicates the management of project documentation and therefore the development of the ontologies and tools it requires.

The flexibility and openness of such projects therefore require custom and proper ontologies so that their documentation can enable the participation of different actors and relevancy for different applications within coherent systems. In order to address this gap, the authors either organised or participated in a workshop in May 2019 that explored how makers could collaboratively develop an ontology for artifacts based on the analysis of the existing different types of documentation required for its replication. The "Ontology of the Open for Open Hardware" workshop took place on Friday 10th of May 2019 within the Creative Commons Global Summit 2019 in Lisbon, Portugal[1]. The goal of the workshop was two-fold: 1) to evaluate the ontological integrity within the documentation of an artifact through the metadata present in its documentation, and 2) to collaboratively prioritise elements that help to unequivocally identify a single entity, that is, to draw a line between what can be considered a single artifact and its reproductions. Therefore, the workshop consisted of two main activities: 1) a group discussion where participants identified definitions described in open hardware documentation (Figure 1), and 2) a closed card sorting activity to determine the level of priority of all these elements (Figure 2). A two-fold set of definitions expressed in the documentation are being considered for defining elements (Svenonius, 2000):

- Conceptual definitions (which express the intentionality of the author towards the artifact). In this regard, conceptual factors refer to the purpose for which the artifact was created and documented. These factors may differ even for similar technological applications, for example, when two Arduino projects developed with similar technical requirements are used for different purposes.
- Operational definitions (in relation to the description of the artifact). Operational factors are related to the steps required for reproducing the artifacts. A change

[1] https://ccglobalsummit2019lisbonportugal.sched.com/event/MiXg/ontology-of-the-open-for-open-hardware

in materials, dimensions or electrical components, for example, will define the manner in which the artifact will be assembled.

For the first activity of the workshop, participants were given the following items:

- A list of 25 metadata cards previously defined from examples of open hardware documentation.
- Open hardware project documentation examples for participants to discuss.

Organised in three groups, participants engaged in the discussion and evaluation of metadata elements that could be identified as more or less relevant for project documentation and were encouraged to write down missing fields that they considered important. Participants were able to quickly familiarise themselves with the documentation and the list of metadata, as well as how authors express some of these elements within the documentation of projects (Figure 1).

For the second activity of the workshop, participants took part in a card sorting game, where cards representing metadata elements were sorted by level of importance for the overall definition of an ontology while trying to avoid duplicate entities (Figure 2).

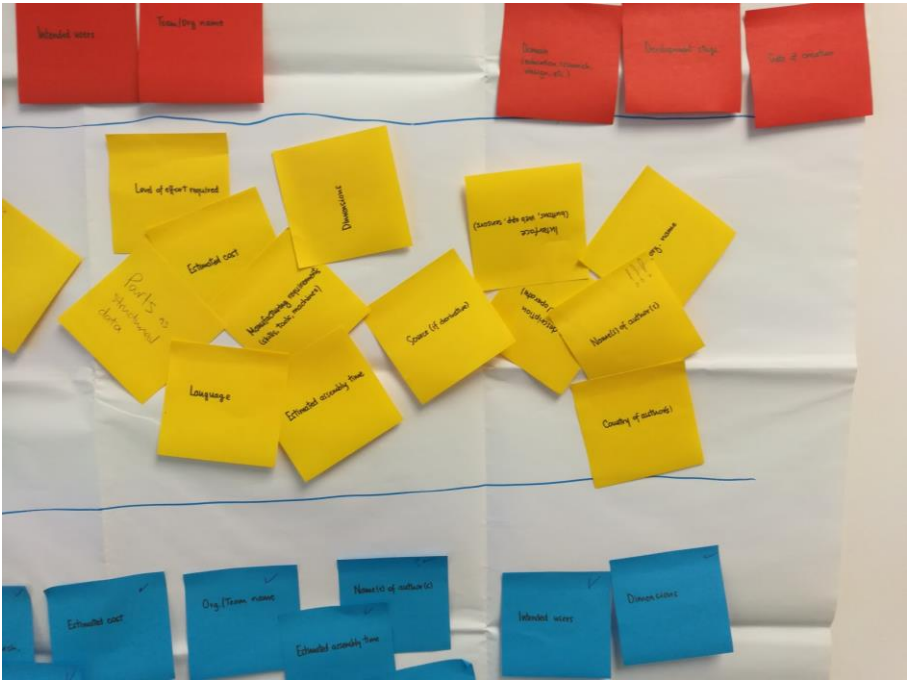

Figure 1. First activity of the workshop.

Figure 2. Second activity of the workshop.

3.2. Results

As results of the workshops, participants elaborated a list of metadata elements that were ranked in terms of their relevance (Table 1). In a total of 28 elements, 17 are operational ones and 11 are conceptual ones: in terms of architecture, an ontology of Open Hardware mainly describes it as a technical effort through the elements, procedures and actors that enable its design, distribution and manufacturing. In terms of ranking, however, the perspective of the participants changes this approach: conceptual elements are generally considered more relevant: the average ranking is 12.9, and for conceptual elements it is 11.3 and for operational elements is 14.0. This disparity might point to a contradiction between the practice and ideals of Open Hardware, or an emerging change in them that it is not tracked yet. The main tension highlighted is between how artifacts are valued by users not only for their physical characteristics but for their intended purposes versus the type of technology, materials and procedures for developing them.

Table 1. Ranking of metadata elements elaborated in the workshop.

Metadata element	Added by participants	Group 1 rank	Group 2 rank	Group 3 rank	Median rank	Definition
Project name		1	3	2	2	Conceptual
Keywords		5	2	4	4	Conceptual
Problem that the artifact solves		7	4	1	4	Conceptual

4. Discussion

4.1 Community-Centred Design of ontologies between practice and research, communities and meta-designers

The workshop described above was prepared by identifying the most common metadata elements of a selection of existing Open Hardware projects, then formatted as cards to be sorted. The aggregation/sorting exercise was done through a set of criteria proposed by the facilitator (for example: level of effort required, estimated costs, assembly time, manufacturing requirements, skills, tools, …) with three possible levels of priority. The idea of designing ontologies collaboratively and the specific methodology proposed was well received by the participants: it provided a good starting point for organizing, prioritising a collection of existing entities and for the discussion and addition of new ones to an ontology of Open Hardware projects.

More precisely, for the specific the audience of the workshop, the emerging ontology shows how Open Hardware is considered as a utility-oriented medium for designing and working, with a strong focus on problem solving, manufacturing and usage of the artifacts it describes. The ontology was designed by participants as the results of their thinking about how they would produce and use the artifacts. This utilitarian and problem-solving perspective can be considered as the result of cultural values of the Open Hardware movement or at least of the participants in the workshop, who thought about the ontology with their practice as a starting point.

A workshop like the one organised is, however not yet representative of a community: participants of the global Open Hardware and Maker Movement communities attended it, but more than a community of practice was a small sample of a community of interest in the Creative Commons licenses and their application. Their practice informed their view of the

ontology, the centrality of community-based organizations in such movements cannot be addressed and appreciated in such a context that was limited in time and space. We therefore propose that a collaborative approach can benefit the design the creation ontologies of open projects, with the active participation of the communities that will develop and adopt them so that their worldview can inform and support their practice and vice versa.

The discussions with the participants brought up how the definition of an ontology emerges from local practices. At the same time, we should also note the role of the facilitator, that by selecting entities and designing the cards and the dynamics of the workshops acted not just as a facilitatory but already as a meta-designer of the ontology, bringing design activities in the facilitation. From these two aspects we propose to consider that both practice and research, community and meta-designers should element of Community-Centred Design of ontologies.

Furthermore, we propose that the main results from the workshop are not a specific ontology tied to a limited audience and with a limited approach to design, but how the reflection on that experience could pave the way for more deep and complex design of ontologies together with communities. We then elaborate strategies for extending the experience, tools and methodology of the workshop to different communities, to be explored and researched in their practice. Given the importance of both design and research, and their ability to redefine ontologies, we suggest adopting Redström's approach for building Research through Design frameworks (2017). Moving from the generic results of the workshop to concrete cases, the next section explores how the insights here elaborated GROUU[2], Make Works[3] and Appropedia[4] design and implement ontology with communities through its digital platform as an artifact towards meta-design. These three cases represent different approaches for addressing the issues of documentation and replicability of Open Hardware and Design projects in the Maker Movement: from a single project (GROUU) to a repository of projects (Appropedia) to a network of manufacturers of projects (Make Works). In all these three cases Community-Centred Ontology Design could be implemented especially in the product, project, program and practice.

4.2 GROUU

GROUU is a current doctoral research with a Research through Design approach, revolving around a set of networked sensors and actuation devices (IoT - Internet of Things) for precision agriculture to be used in diverse agricultural contexts. GROUU aims to democratise precision agriculture sensor networks and automation, addressing the effectiveness of knowledge transfer once tests and community implementations are valid and working. By

[2] https://github.com/steam228/GROUU - https://wikifactory.com/+grouu
[3] https://make.works/
[4] https://www.appropedia.org/Welcome_to_Appropedia

aiming to digitise Tacit Knowledge and transfer it between users, GROUU is also exploring the possibility of having IoT as a digitisation and knowledge transfer media. The goal is to extend the implicit knowledge conversion through the socialisation model proposed by Nonaka and Takeuchi (1995) to a digitally mediated data sharing and usage ecosystem. The design of standardised ontologies can achieve this for the Internet of Things, maintained through documentation and versioning protocols.

The Research through Design strategy (Figure 3) sees GROUU at the product level, consisting of multiple open hardware, software and design sources developed within a doctoral research (program) revolving around the redefinition of criteria for Open-Hardware-mediated knowledge transfer design and evaluation (project). These are connected with the practice of the doctoral candidate and experienced farmers involved in teaching each other best practices in farming. Finally, the paradigm connects all of these with the main trends of Pervasive Computing, Embodied Cognition and Tacit Knowledge conversion: this strategy would connect knowledge transfer to media digitisation; the research of new roles for existing technologies could democratize its access.

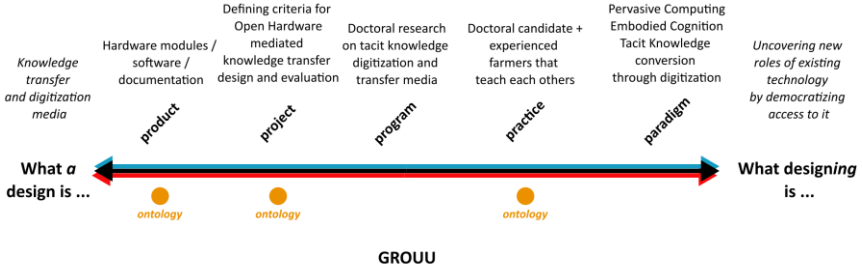

Figure 3. A Research through Design strategy for ontologies in GROUU.

4.3 Make Works

Make Works is an open source online directory for manufacturers, makers, material suppliers, and workshops to make local manufacturing openly accessible to anybody. The digital platform allows designers and makers to find manufacturers, material suppliers and workshop facilities in their local area to produce their artifacts in a distributed manner. Make Works operate in six regions: Scotland, Birmingham, Derby & Derbyshire, UAE, Sweden, Catalonia. Ontologies in Make Works describe specific regions and their manufacturers in terms of industries, materials, processes and machines.

The Make Works team's goal and, therefore of its Research through Design strategy is to explore with Action Research how to develop the platform by considering diversity,

inclusivity, and accessibility. The aim is to avoid reinforcing one single point of view to all the regions, enabling each community voice to be heard and agency with an approach inspired by Fraser's social justice framework of representation, distribution and recognition (1998).

In its Research through Design strategy (Figure 4), the digital platform is the product part of a project made up of several platforms for connecting makerspaces, designers and manufacturers (who constitute the practice). The bottom-up factory listing process is guided by a specific Make Works Handbook that defines the program since it bridges practice and research and informs their workflows. The Handbook describes the starting, co-designing, operating and running of new regions with context-based contributions and suggestions. Finally, Social Justice, Distributed Design and Manufacturing represent the overall paradigm informing all of these. This strategy would then connect locally produced artifacts with designing networks of distributed design and production.

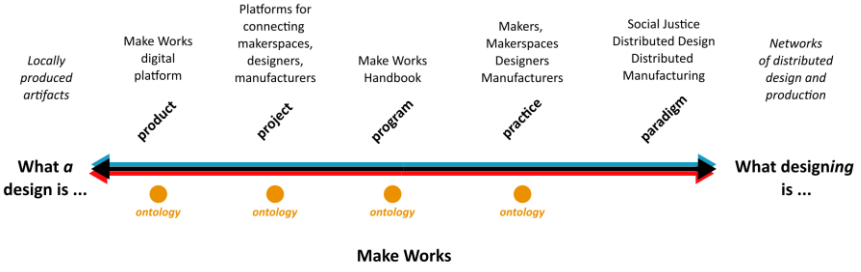

Figure 4. A Research through Design strategy for ontologies in Make Works.

4.4 Appropedia

Funded in 2006, Appropedia is one of the main wikis dedicated to sustainability and international development. Its community focuses on the documentation of open source appropriate technology (Pearce, 2012), and currently hosts hundreds of appropriate technology designs developed by its community. Ontologies in Appropedia comprise these categories: a) a description by the author of artifacts and tutorials, b) contextual applications of technologies in different conditions and through design decisions, and c) impact validation by users in terms of the Sustainable Development Goals or other domain-oriented impact frameworks. Appropedia aims to align its ontologies with the Open Know-How[5] standard to reflect manufacturing capabilities and contextual aspects related to replication and impact to the ontologies.

In its Research through Design strategy (Figure 5), the platform's documentation functionalities are the product to be developed, while the platform is the project. Open

[5] http://openknowhow.org/

research of appropriate technology is the program connected to and informing the work of design students, researchers, designers, makers and non-profits. Finally, Open Source, Open Design and Hardware and Appropriate Technologies represent the overall paradigm informing all of these. This strategy would then connect the documentation of the design and manufacturing of open artifacts with researching open source appropriate technologies.

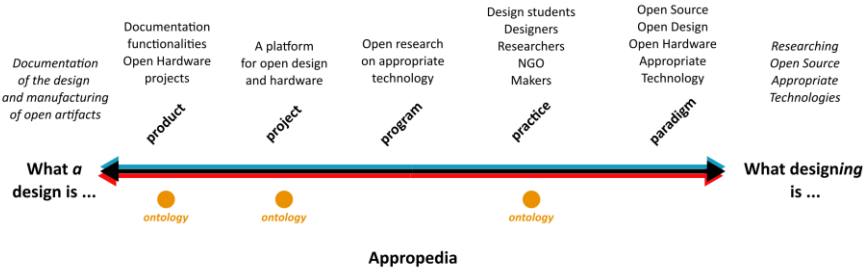

Figure 5. A Research through Design strategy for ontologies in Appropedia.

5. Conclusions

The lack of standardised guidelines and ontologies for Open Design and Hardware create communication barriers and pose a problem for discovering these artifacts through machine-readable search engines and, therefore, ultimately to services and platforms for designers. This paper argues that a collaborative approach to the definition of ontologies could provide an exciting direction for creating documentation tools for developing and managing Open Hardware and Open Design projects and processes. Furthermore, exploring this direction could also improve our understanding of how a design approach could work with ontologies and digital technologies while enabling designers to reflect upon the nature of their practice and its impact on stakeholders' cultures. Overall, this research points out how engaging communities in developing their technological infrastructure has far broader implications about design and its role in supporting collaboration and its practice, research and culture. This paper also contributes to the emerging approach of Community-Centred Design (Meroni & Manzini, 2014; Villari, 2013) by expanding its focus towards data ontologies and local worldviews. Through a focus on the community dimension, Community-Centred Design has extended the scale and complexity of the engagement of users in design processes and projects further beyond Participatory Design and Co-Design (through their engagement as individuals), User-Centred Design (through analyses of their needs) and User-Experience Design (through analyses of their experiences). This approach further adds a focus on the analysis of the communities' worldview of how design processes and projects are structured (ontology as a worldview) by linking it directly to the development of digital tools and platforms that would support their engagement (ontology as a data format)

(Menichinelli, 2020). This approach enables designers to develop digital tools directly linked to how communities perceive and consider intangible entities such as design processes.

In this paper, we present the results from a workshop that explored the prioritisation of domain concepts through a game of card sorting/generation to classify the elements of an ontology. Furthermore, we elaborate insights and Research through Design strategies towards integrating the design of ontologies with the participation of users and their communities, bringing Community-Centred Design to ontology engineering as both Meta-Design and Ontological Design. The approach was well received by the workshop participants and provided content for the elaboration of several insights. However, such contents and insights are constrained by the limited context of the workshop. Further research should expand them by working directly with communities with an Action Research and Research through Design approach to give them an active role. For these reasons, the paper contains three Research through Design strategies for co-designing ontologies in three different examples of Open Hardware and Design projects within the Maker Movement: from a single project (GROUU) to a repository of projects (Appropedia) to a network of manufacturers of projects (Make Works). Thus, further research is important for improving the workshop structure and methods, extending to more elaborated methods and testing and implementing the Research through Design strategies in real life.

Contemporary Spaces of Apparel Design: Embracing both Digital and Physical Environments

Krissi Riewe

Kent State University, Kent, OH USA
kriewe@kent.edu

Abstract | The juxtaposition of digital technology with the physical environment has changed the way humanity moves through life, contributing to complex relationships with our surroundings. Spaces are no longer limited to the tangible as computer screens become portals to auxiliary environments, altering perceptions of distance and time. The relationship between the hand and material object has changed as the work of design blends virtual and physical spaces requiring agile design thinking. This article examines these digital and physical spaces through the lens of a reflective creative apparel design practice, specifically investigating the use of the digital textile printer alongside traditional garment-development methods. Craft and technology discourse provide a framework for using these spaces by analysing them as tools in the making arsenal. Here, by acknowledging the contemporary design environment and embracing the juxtaposed digital and physical spaces for design, an innovative workflow is established that encourages improved design and making systems.

KEYWORDS | DESIGN ENVIRONMENT, APPAREL DESIGN, DESIGN THINKING, TEXTILES, TEXTILE PRINTING

1. Introduction

The juxtaposition of digital processing devices with the tactile, physical environment has changed the way humans move through life, contributing to a more complex relationship with time and place. The time required to accomplish tasks, communicate overseas, or move across the globe has been shortened, and immediacy of results is celebrated. Life's activities are now nearer each other in time, making the places these events occur nearer in thought, if not nearer physically. Because digital technology is a driving force behind this shift, product designers must consider how this affects the making process, the product being produced, and how the product will be used. Much design work is now conducted digitally, in a space where new hand and machine relationships are established. Working through a screen instead of manipulating physical objects allows for experimentation in design with the ability to "undo" actions or test multiple versions without committing to irreversible manipulation of materials. Design iterations are interconnected and virtually side by side for evaluation. This article looks at the digital design environment through the lens of a reflective creative design practice, uncovering how this environment operates as a space for innovative design thinking. Specifically, it investigates the use of the digital textile printer alongside traditional garment-development methods to seek out innovative processes through the development of a body of work using "making as a way of generating design knowledge." (Loh, et al., 2016) It focuses on how both physical and digital design environments work as complementary tools that work in tandem rather than focusing on pre-programmed tool or computer program purposes; for as the more focused these purposes become, their range of creative use is limited. (Albers, 1971) Theoretical craft approaches to making provide a framework for using these digital and physical places by analyzing them as tools in the making arsenal; when these tools are combined with creative play, risk-taking, and design thinking established processes are challenged and pushed towards innovation.

Digital tools and processes are introducing significant changes to the way the apparel design industry operates, including the way clothes are produced. Traditionally, a skilled patternmaker using draped muslin and paper patterns would develop sewn samples that would allow direct evaluation of aesthetics, functionality, and material choice. Modification to the sample required additional versions, and unless a complete re-make is developed the original is lost. With the development of digital platforms, programs such as Adobe's Illustrator and Photoshop, Optitex, Gerber, Browzwear, and CLO 3d provide both 2D and 3D spaces for apparel design and development. Within these constantly evolving technologies, the designer can save multiple versions, experiment with aesthetics and construction, and plan order of operations in the digital space before consuming physical materials for sampling. However, a design on a screen can only understand the nuances of physical material qualities as well as a person programming or using the machine understands them. (Albers, 1971; Edwards, 2000-2001; McCullough, 1996) This suggests that a relationship between processes would be more efficient and innovative.

To develop this relationship, the physical and digital design spaces can be organized and understood as tools. Through this lens we examine how designers might work to problem-solve by combining process and material knowledge the with use of the most appropriate tools. The impact of this designation of tools could be approached from several points of entry, but as it involves the work of designing itself a practice-based approach is taken here. Within this research framework, the development of a capsule collection of garments incorporating both digital and physical tools is evaluated. Current fashion design processes are often problematic, and instead of solutions that are merely "modifications of these undesirable practices and the status quo," (Fletcher, 2014) this approach to the design process encourages the designer to experiment with new methods. In this work, using a practice-based methodology generated information from a maker perspective, supporting research of the design process; while this kind of research remains context-specific, it enables design research to operate as an "open system, one that is networked, responsive, and expanding." (Vaughan, 2019)

2. Contextual Review

This research seeks to describe a progressive relationship between the digital and physical spaces of design by analyzing the design process, and it draws from previous research on design, making, and apparel design, with both long-standing sources as well as contemporary articles valuable knowledge contributors. Because using available resources as tools to manipulate materials frames this work, craft-based discourse is highly relevant; additionally, while today's fashion and apparel field is a global, corporate industry the process of designing and assembling clothing has roots in craft as well. (Lou Taylor, 2004) Important to include here is the use of the terms "garment" or "clothing" instead of "fashion" in this article; Yuniwa Kawamura explains that "items of clothing must go through the process of transformation to be labeled as fashion" (2005), and here we will not be concerned with the sociological and semiotic transformation of the clothing object. Instead, we will focus on the designing and making process. Fiber artist Annie Albers's text *On Designing* describes the dance between functional and aesthetic concerns, and how this affects the maker's use of tools and materials; David Pye also writes about tools and the making process in *The Nature and Art of Workmanship* and *The Nature of Design*, providing a basis for making sense of balancing knowledge and skill with taking the risks needed to innovate. Bringing this into the contemporary lens, an article by Loh, Burry, and Wagenfeld is an example of how Pye's theory on the complex relationship between tools forms a repertoire, one that includes both the digital and physical. Additionally, these sources are examples of how knowledge can be gained through the kind of practice-based design research executed here.

Sources affirming the validity of digital technology for creative use within craft and apparel applications is helpful for both theoretical and methodological purposes. David Pye and Annie Albers contribute perspective on the relationship between hand-crafted methods and

contemporary technology, while Malcolm McCullough describes how computers and software are virtual tools for developing and making. McCullough expounds on both of these concepts in *Abstracting Craft*. Taking this further, Dreyfus and Dreyfus explain the importance of human intuition and expert skill in the use of these tools in *Mind Over Machine*. While this text focuses on robotics and spends time addressing fears around the development of artificial intelligence, the debate between the power of computers versus the experience-led wisdom and intuitive understanding of a human mind provides a useful model to follow when balancing logistics and innovation. The 2001 *Manus-Machina* exhibition catalogue by Andrew Bolton showcases the use of digital technology in apparel design and is important to reference for perspective on using digital tools to make clothing. Because this work involved developing original textiles, sources such as *Digital Textile Design* and "Design Thinking for Textiles: Let's Make it Meaningful" provided theoretical and methodological guidance.

3. Theoretical Framework

Textiles have long been used by humans to make garments that cover, adorn, and protect, and the garment manufacturing process has progressed along with advancements in better tools and new technologies such as the sewing machine. Additionally, social changes such as the industrial revolution and the rise of fashion houses at the turn of the century has led to the development of a complex, fast-paced industry that relies on digital design and communication to maintain. Before the current disruption from the coronavirus pandemic, this fashion system left little opportunity for the designer to think or work outside established systems of making clothes. The more regimented each step in the development and making process becomes, the less creativity or skill is necessary (Edwards, 2000-2001; McCullough, 1995); with regard to tools, the more focused they become, their range of creative use is limited (Albers). The fashion industry focuses on economies of time and money, and these processes settle at the most efficient balance of these with "best" ways of manufacturing generally evaluated in terms of their cheapness rather than ethical or environmental concerns. (Fletcher, 2016; Pye, 1964) Coping with the pandemic's effects on supply-chain logistics and changing consumer buying habits is requiring a new perspective on these priorities, such as a re-connection of time between seasons and collections. (McAlpine, 2020) To help guide us towards the sustainable systems changes often called for in current fashion discourse (Bowles & Isaac, 2012; Fletcher, 2014; Gwilt, et al., 2011) as well as those demanded by the effects of the pandemic, we can look at theoretical models for working creatively outside previously established systems. This idea is supported in Pye's (1968) theories on making, which acknowledge the safety in working within proven methods but also recognizes that taking risks is the only way to innovate, requiring a designer's intuition and dexterity.

The digital environment of design, encompassing both 2D and 3D computer CAD programs, is itself a contemporary design and making tool allowing "Concepts [to] become things. We

can't touch them yet, but we can look at them, point at them, and work on them as though with hand-held tools." (McCullough, 1996) While this opens opportunities for innovation it also enables the simplification of complicated process and the automation of physical tasks – a capability that contributes to mental de-skilling as well. (Edwards, 2000-2001; McCullough, 1996) This defeats the exciting possibilities for creative risk-taking and innovation, converting the digital design environment into "a means to an end." (Loh, et al., 2016) Dreyfuss and Dreyfuss explain that a computer is a logic machine that is an "ideal beginner," and an expert is needed to use the tool in an innovative manner; with expertise and intuitive decision-making the user can challenge pre-programmed uses. McCullough supports this, stating that "masters respond to context, even when doing so means breaking the rules;" this also encompasses the "…exploration, improvisation, and, to use the simplest word, play." (1996) When we simply collect processes to repeat, we do not construct new knowledge. (Albers, 1971)

The theoretical framework for this research is based on a craft approach to making, and by understanding the relationship between designer/maker, tools, materials, and end product we find a framework that encourages educated, creative, and methodical risks to open opportunities for innovative discovery. As Pye stated, "Tools of themselves make nothing," (1964) and are limited to what they are used to accomplish. Without design thinking, or the "creative input and designing workflow from the practitioner… such toolsets remain outside the practice." (Loh, et al., 2016) A designer with expertise in managing both digital and physical spaces of design in a symbiotic manner is needed to navigate the ever-evolving technologies that affect materials and tools. (Bye and Sohn, 2010; Carden, 2016; McCullough, 1996)

4. Process

The collection of garments completed for this work initially began as two separate tracks of design experimentation: one using traditional draping, patternmaking, and sewing methods, the other experimental prototyping using the digital design space. (Figure 1) Both directions sought to uncover design and making processes that would maximize the designer's creativity, reduce material waste, improve emotional durability, and serve functional and aesthetic user needs. Open-ended experimentation and design "play" (Flanagan, 2009; McCullough, 1996) within these spaces soon merged, as intersections between processes began to surface and the capabilities of each environment benefited one another. The result was a larger body of creative design research exploring this relationship, primarily incorporating patternmaking and sewing skills with the use of Adobe Photoshop and Illustrator to develop original textile designs. The researcher's twenty-plus years of patternmaking and sewing experience provided expertise in using textile materials and contributed an intuitive ability to manipulate shape and silhouette to minimize fabric waste. This was combined with dedicated research on the proper operation and capabilities of the digital textile printer. Use of textile printers began as early as the 1960s, and with

improvements in quality, speed, and accessibility these tools have contributed to connecting garment and textile design. (Bowles and Isaac, 2016) With these printers, designers can develop and design conceptually and aesthetically in a digital environment before committing to using actual resources. (Bowles and Isaac, 2016; Carden, 2016; McCullough, 1996) Furthermore, the digital printing process consumes far less water and energy, minimizing environmental impact. (Bowles and Isaac, 2016) In this way, the textile printer enables development and execution of creative, innovative, and less-wasteful garments; for these reasons, use of this particular technology became the fabrication tool spanning the digital and physical space.

Figure 1. The body of work completed in this practice-based research. The look in the far right uses the textured textile made from the motif components in the jacket.

The process of designing and constructing the garments integrated digital and physical spaces from the beginning. Garment patterns were physically developed using draping, flat patternmaking, and muslin sampling; simultaneously, textile print designs were developed digitally in Adobe photoshop. A snapshot of the *Castilla coccinea* wildflower provided the base motifs of the print; these were modified to adjust scale, contrast, and tone. By working in both spaces simultaneously, the textile and garment designs were developed in a complementary manner; volume and proportion created interest as well as highlighted the print designs. After developing the physical paper garment patterns and printing several successful 8”x 8” textile samples, the garment patterns were digitized and placed in photoshop to be joined with the textile print. Here, via the screen, the logistics and aesthetics of the project could be evaluated before moving forward. Several design problems presented themselves. First, the garment pattern pieces did not efficiently nest

within the printing area, leaving significant waste material. Second, the print scale was not appropriate for all applications on the garments. Additionally, the engineered prints and stripes did not match the intended pattern pieces perfectly.

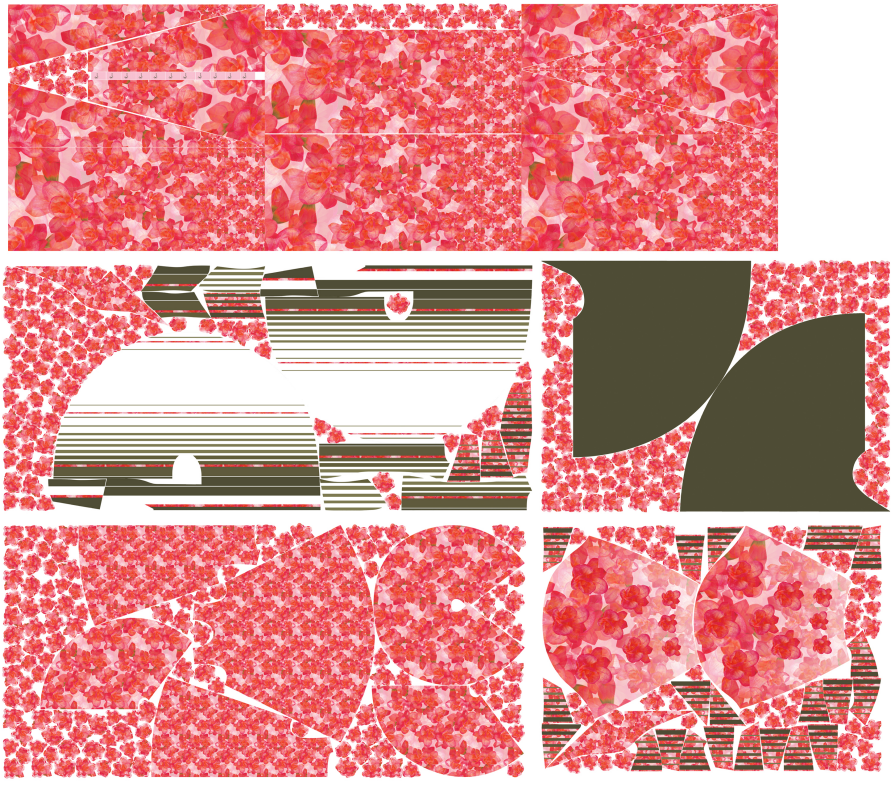

Figure 2. The print layouts were completed in three- to five-yard increments. Tight nesting of the pieces was considered; filling in empty spaces are the smaller motif pieces.

To resolve these design problems, knowledge of the advantages of both digital and virtual places of design was employed concurrently; as a result, the plan for the printing process shifted from producing repeat print yardage to engineered printing. (Figure 2) This allowed the prints to be placed directly on the garment piece in the proper location, and the pieces from various garments could now be intermixed on the blank yardage to enable better nesting and create less waste. Correcting the textile print scale was easily done by digitally developing several versions to compare in relationship to the garment silhouette and body shape. Despite these modifications and a meticulous print layout, the printing process still left a significant amount of textile waste. Smaller pieces were needed to fit within the spaces of the layout, leading to the development of an additional garment that could utilize small,

repeatable components. Using the individual print motifs as component pieces, these were placed in every crevasse of the print layout, allowing significantly more of the raw textile to be used. (Figure 2) The yardage was printed, and the larger garments pieces were cut and sewn while the motif areas were arranged and placed in the laser-cutter to create hundreds of individual shapes. These were then attached to a base textile to create an entirely new textured fabric. (Figure 1) The resulting body of work represented a workflow incorporating physical and digital spaces as symbiotic tools enabling both resources and creativity to be maximized.

5. Analysis

Digital printing allows for flexibility in surface design through color, scale, and placement, and the juxtaposition of the physical and digital places of design using traditional knowledge alongside emerging technology created avenues for developing on-demand customization, accessible creative branding, and forward-thinking methods of making clothing. The open-minded view of incorporating these resources during the process is key, encouraging treating materials as a direct source of knowledge through direct material handling (Marr & Hoyes, 2016) and allowing the maker to respond intuitively when working in both physical and digital spaces. With this approach, they are used strategically as symbiotic tools and the space and time between tools is narrowed allowing design problems to be recognized quickly and resolved digitally. Logistics within the digital environment presented solution options, while knowledge of how the physical material would be sewn, constructed, and draped in the final printed textile material guided the final design solution. This illustrates how an agile, flexible, and resource-led attitude towards tools and materials enables the designer to understand and execute solutions. Risks were managed or worked out digitally before commitment to physical goods, and intuitive experience challenged the digital solutions to their fullest potential.

The designer is more capable of experimenting with methods that lie outside established systems and can develop ways of working that resolve problems such as those within the apparel industry. The challenges facing the industry include adjusting to significant changes in how products are produced, marketed, and purchased – an issue highlighted by the coronavirus pandemic – while resource-depletion, pollution, and ethical manufacturing remain problematic. A new perspective on the processes of design, including a holistic, resourceful view of materials and tools enables the designer to have greater impact through design thinking and incorporating solutions within the design, for “Change only begins to occur once practitioners come to understand the potential of new technology and are comfortable with it.” (Bowles & Isaac, 2012)

6. Conclusion

How we value and nurture the relationship between digital and physical spaces of design is critical to future innovation. Through applied design research and consequent reflection on that practice, a new workflow that shrinks the distance between the digital and physical environments emerged. Because this design research focuses on the tools and materials within each space, by framing these disparate design environments as tools or "toolchests," the focus moves from an isolated or independent approach to an integrated one that allows the practitioner to use creativity and intuition to design a better workflow. (Loh, et al., 2016) This relationship between digital and physical tools assists the removal of limiting processes and tools for their intended purpose only, for "the more we learn how to do, the less we know what to do." (McCullough, 1996) Guided by design thinking, the work of designing becomes an intentional, problem-solving activity as a result, and a more circular or responsive way of using materials and planning production occurs. Specifically related to this practice-based research we also see that "Design thinking is not a commodity, therefore the act of making textiles is more than a series of steps on the road to new product development and innovation." (Valentine, et al., 2017) The work of designing using traditional garment-making methods alongside the digital textile development provides an example of how we can approach design in a contemporary manner.

A re-thinking of the apparel industry as a whole is often called for in discourse addressing concerns about resource sustainability, ethical manufacturing, and pollution (Fletcher, 2014; Gwilt, et al., 2011), yet recommended solutions are limited to modifying specific parts of the larger system or discussing larger theoretical approaches. However, these parts are interconnected, and focus on an isolated area limits effectiveness; furthermore, consumers expect both aesthetics and functionality, and both must be addressed. When either is highlighted, the designed object is limited, and this segmentation "arrive[s] at separate instead of at a single, all-inclusive form that embodies the whole of our needs." (Albers, 1971) The designer is at the heart of this complex system, and "From the centralized position the designer can influence and impart new (sustainable) information that aids in the design and production of 'better' garments." (Gwilt, et al., 2011) This places responsibility on the designer as a driver of systems change; with a contemporary perspective and understanding of the tools at their disposal they are better equipped and empowered to effect change. The industry is undergoing a seismic shift, and the various technologies being introduced are yet to be fully understood. But if we organize our perspective by considering the positive impact of condensing the space between these tools through physical and digital capabilities, the possibilities for developing innovative solutions to many of the challenges facing the fashion industry are reachable.

This suggests that we not simply look at what each place of design offers individually, and that we look beyond designing in a linear manner. This particular body of work began as disparate exploratory tracks, yet the contemporary design atmosphere requires collaborations of resources, including tools. The models of design and business planning are

undergoing an accelerated transformation requiring agility and progressive thinking. This requires organization of methods and tools, or the designing of a path to begin "mastering your means to the point they no longer interfere with attaining your ends." (McCullough, 1996); brands and designers who embrace intentional, thoughtful incorporation of digitization within the entire the design development process will be equipped to survive the coronavirus pandemic and become part of a more sustainable, evolving new workflow. Considering environments or spaces of design as tools provides that organization, and by educating current and future designers, product developers, and makers how to harness the physical and digital places of design as tools in the making arsenal, they will be better equipped to balance the value of human understanding, empathy, and intuition with logistical, algorithmic, digital technologies to thrive in an increasingly virtual and data-driven world.

Design Cultures of Making: Fashion thinking as creative process and pedagogy

Susan Postlethwaite

Royal College of Art
susan.postlethwaite@rca.ac.uk

Abstract |This paper shares research being developed through an Art and Humanities Research Council, Creative Industries Cluster funded 5-year project, the aim of which is to transform the competitiveness, agility and creative output of the UK's fashion industry. Its focus is to develop innovative , multidisciplinary STEAM+D based fashion designers, industry facing training , and education for post graduates fashion students, breaking down traditional fashion and technology silos.Through their work a group of researchers at the Royal College of Art attached to the Future Fashion Factory Project (FFF) propose fashion thinking as a new rational for fashion education that has three distinct strands – fashion thinking for social-change, fashion thinking for applied specialisation and fashion thinking through advanced manufacturing. Fashion thinking through advanced manufacturing is discussed here highlighting Discourse, a tool developed to enable investigation into current pedagogic models, and revealing the importance of developing new language competencies for fashion.

1. Introduction. The Creative Industries and Manufacturing Landscape in the UK.

In the Executive Summary 2020 ,Manufacturing the Future Workforce, The High Value Manufacturing Catapult recognised that the overall contribution manufacturing made to the UK economy was in decline but the government wanted to make the UK more competitive in this field. The counter narrative developed through the Creative Industries Federation, the independent body which claims to represents, champion and support the UK's creative industries, stated that the creative industries were growing at more than twice the rate of the UK economy. However, there was a recognition that UK creative industries were under-capitalised, suffered from skills shortages and were hampered by a lack of diversity and unequal access to opportunities. Agility, new skill sets and a younger workforce were seen as imperatives to greater success . The Creative Industries Manifesto (Creative Industries Federation Report 2020) proposed equipping the next generation of the workforce through returning creative education to the heart of the curriculum. Countering this, the Longitudinal Education Outcomes data (LEO,2019) suggested studying for an arts and humanities degree did not enable graduates to earn significant salaries by age 29 when compared to economics or science graduates , with a sub narrative that undergraduate courses in art and design do not contribute significantly to GDP. The Creative Industries Manifesto suggested that metrics beyond salary were urgently needed to capture the true value of creative education. Wider measures such as social value, creative achievements, and civic contribution must be recognised they claimed.

A complex narrative and counter narrative are still developing in UK politics involving the creative industries, manufacturing and higher education. Post the UK leaving the European Union many policies will be rewritten and new strategies developed that will impact all 3 sectors and their relationship to each other. Recently published reports commissioned by the UK Government suggest a confusing picture of claim and counter claim focusing on the value of an arts and humanities education and its contribution to the UK economy. These include a new industrial strategy document and the Ten Point Plan for a Green Industrial Revolution Building back better, supporting green jobs, and accelerating our path to net zero (2020). The tide may even be turning, back in favour of the creative industries due to the devastation caused it in the UK by the pandemic. It is within this fraught landscape that UK art and design schools are being challenged for their relevance and may need redesigning for a more agile future.

2. Creative Industries Clusters Programme. Future Fashion Factory.

In 2018 the Creative Industries Clusters Programme funded by the Arts and Humanities Research Council invested £80m in eight new creative research & development partnerships

bringing together the UK's creative industries with the university sector. This programme was proposed as a catalyst to further grow the creative economy unlocking emerging fields and adapting new technologies. Part of the UK Government's Industrial Strategy Challenge Fund, the programme proposes to drive economic growth through the development of new products and services to address some of the problems of skill shortage, an aging workforce, lack of agility and so on.

The 5 year project funded through this programme and jointly held by RCA, the University of Huddersfield and the University of Leeds focuses on industry-led challenges in which designers are at the fore front of the creative process, applying, co- developing and implementing new textile and industrial digital technologies in collaboration with supply chain manufacturers and other technology experts, in the high value luxury textile and fashion sectors. Developing a new skillset for designers is central to the project as the research focuses on developing two key themes: Digitally Connected and Sustainable Processes and Digital Communication Systems. The RCA is tasked with developing research from both themes to address the identified skills gap in the industry where multidisciplinary designers trained in a unique combination of art, design, science and technology competencies linked to the STEAM+D agenda might answer the need for a newly skilled workforce.

Through FFF the RCA is working with multiple industry partners assessing, from a designer's perspective, how new technologies might be configured and implemented as they are developed. The disruptive influence on the way that business in fashion design is done is being explored by RCA researchers who have received additional funding through the AHRC to be trained in design anthropology and ethnographic methods. Design Anthropology takes the future oriented nature of design and marries it to participant observation as a key component of anthropology, setting itself the challenge of developing tools and practices for collaborative future making. Design Anthropology integrates anthropology's rich tradition of contextualisation and interpretation into the tasks of design, emphasising the generative role of theory in developing design concepts and critically examining existing, often implicit conceptual frameworks. (Ton, Otto and Smith 2013). This approach , married to an examination of Design Thinking and Textile Thinking, an engagement with Transition Design theory, Theory of Change protocols, practise based and practice led research methods will be developed over the course of 2021 and shared through a book sprint and podcast.

3. Fashion Education: Old & New Models of Pedagogy

Traditionally focused on training students in conceptualising, designing and making of their own collections, most undergraduate and postgraduate fashion courses in the UK have not significantly evolved over the past 25 years. They appear to be increasingly unsuccessful in training students to enter a world of advanced manufacturing, relying on machinery and manufacturing processes that have not changed significantly in over 100 years. Design

students are not trained to work with digital tools, leading manufacturing systems or engineering technologies or in the development of new models of entrepreneurship or circular economic models that now make up the fashion industry landscape. Nor are the students being equipped to address societal and environmental concerns in the rigorously informed way demanded by both industry and consumers.

Reports from Fashion Industry Journal Business of Fashion (State of the Industry Report *McKinsey & Company/ Business of Fashion* 2016) showed that students entering the jobs market were lacking knowledge specific to new technologies resulting in impaired ability to challenge current practice or develop new design-led roles. The future of the UK Fashion Design School may depend on these new insights. Multi-disciplinary universities in the UK have already understood *design thinking, speculative design, and critical design methods (Rogers and Bremner 2019. p.5)* as useful approaches to innovation and are leading the way in research for new economic models of values led entrepreneurialism and the design of 'volume to value' business models that are profitable without growth. As Rogers and Bremner (2019 p 4-5) suggest any repositioning of design education 'must first acknowledge that it has been complicit in creating a world that nobody wants any more'. They recognise a shift in UK Design School approaches in a journey from an emphasis on design, to a desire to 'gain academic legitimacy' establishing dialogues with history and scientific and philosophical theory, then a 'search for legitimacy through design science' and finally a push towards interdisciplinarity 'in an allegiance with technology'.

4. STEAM+D

STEAM as a new industry facing pedagogic model originated from Rhode Island School of Design (RISD). Researched over the course of 4 years from 2011, and driven by an understanding that design education fosters critical thinking and comfort with risk taking , RISD's ambition was "to reach consensus among disciplines on the requirements of the 21st Century workforce" (Allina, 2019.pp 32). In the United States the understanding of the value of design to advanced manufacture is well established, where RSDI considers design to be a literacy, a capability and a specialism. The Design Council Report *Designing a Future Economy- Developing Skills for Productivity and Innovation 2018* suggests that design skills are the fusion of creativity with technical ability and interpersonal competencies. They highlight moving from STEM to STEAM+D - that is, Science, Technology, Engineering, Art and Maths, to include D, the Design element, to ensure a resilient economy in the longer term. The report encourages policy makers and education providers to consider how they will develop the complex problem solving, critical and creative thinking abilities that are essential to innovation (Design Council 2018).

In their *Leading Business by Design: High Value Manufacturing* report the Design Council (2015) the policy recommendation was that young people at all stages of education require exposure to the multidisciplinary mix of science, technology, arts, humanities and enterprise

that should underpin both creative and manufacturing success in the UK. They go on to say that government should provide incentives to universities to deliver an increased range of multidisciplinary design courses in partnership with expert bodies to enable engagement with *the fourth industrial revolution*. The RCA introduced the STEAM approach to its programme delivery in 2016 as part of its strategic plan announced in the Vice Chancellor's report 2016/17. The report stated that developing new models of postgraduate, research-led design education are key to the delivery of a distinctive STEAM education at the RCA. The evolving pedagogical model adds research-driven enquiry, applied through knowledge exchange with industry and through dynamic and 'live' curriculum developments. This research is frequently inter- or multidisciplinary in character, the RCA being the UK's most research-intensive art and design university.

The RCA's 2016–21 Strategic Plan outlines the roadmap for the development of the university's taught programmes. Over the planning period, it is developing new programmes to ensure that it remains at the forefront of art and design education. The RCA is supporting design development through an interface with three core scientific disciplines: computer science, materials science and robotics. Around 11% of the students hold a first degree in fields beyond art and design, for example medicine, finance, law or engineering. These students bring knowledge and expertise from previous careers, and find new, creative applications and solutions through studying at the RCA. The LEO data (2019) supports the proposition that it is through a mixed and interdisciplinary training, particularly an undergraduate degree in science and engineering, married to a post graduate design degree that enables graduate earnings to substantially increase. The Fashion Programme at RCA has seen many more students apply with first degrees in maths, biological sciences, architecture, and computing.

The basic principal of Industry 4.0 is that by connecting machines, work practices and systems, businesses are creating intelligent networks along the entire value chain that can control each other autonomously. UK fashion students have been trained to become micro businesses and then Small to Medium size Enterprises (SME's) and UK Government research funding has targeted small-scale enterprises through research with UK universities like the Creative Clusters Programme. This strategy looks as if it may pay significant dividends in the new post pandemic business environment . *McKinsey & Company/ Business of Fashion* (2019) recognised a new role for small players where they might support R &D for larger brands in in-house labs, or attached to universities as Learning Factories designed as a simulation to enable experiential learning as happens in European technical universities. It is proposed this is where the RCA could lead the way, embracing new technical, economic and sustainable challenges. The linking of small designer business to offshored volume producers had been developing at speed through designers' bench and desktop factory technologies - pattern cutting tools that enable digital development of pattern files that can be sent anywhere in the world via digital networks. An example of how fashion designers are needed to engage with these new industry paradigms can be demonstrated by the fact that these tools do not currently serve the industry well. They do not provide accurate enough fit, that

is, how the pattern fits together and then fits on the body. The systems have been designed by engineers, excluding fashion designers from the initial design process, and in the workplace, where the technology needs to be operated by a skilled technician. The systems serve lowest common denominator manufacturers where speed and cost over pattern accuracy had become the dominant metric over design and fit. This had led, it is argued, to the huge problem of too cheap, undervalued clothing ending up in land fill. Challenging a mindset that proposes "just about accurate" as good enough is where the designer/ researcher's value lies.

5. Fashion Thinking – A New Model

Initial FFF/ RCA research reveals the necessity for training a new type of multidisciplinary fashion student/researcher/designer who can rise above existing "siloed" training structures and who has the intellectual capacity to question, hold to account, and design within, emerging and evolving new industrial models. RCA Future Fashion Factory researchers have proposed and are developing three new directions which can be viewed as distinct, but also linked and coupled, to co generate knowledge and form new propositions for designer led research and practice. Beyond Skov and Melchior's (2010) identification of an object based /culture based /practice based and production-based approach this research supports the following positions:

Fashion thinking for social change proposes following a humanities trajectory, looking at systems for sustainability and bio design as well as user experience, informed by psychology and new economic models. The future of meaningful work, infrastructure change and workers' rights fall within this remit. Neo colonialist perspectives are challenged.

Fashion thinking for applied speculation develops criticality, assessing movements within the industry to test fields of application contextualised by new textile and digital technologies, aesthetics, philosophy and science. Circular economic models, their 'complex web of logistics' and scalability problems (BoF 2020) are explored for long term solutions. The ethics of new technologies are also challenged within this paradigm.

Fashion thinking for advanced manufacturing encourages work that radically reimagines making processes, machines and systems from a designer led perspective within the context of Industry 4.0. Degrowth and just in time economic models, agility in manufacturing, scalability and adaptability, R technologies (Stahel 2017) and reverse logistics are developed here.

A series of 'platforms' designed to support engagement with these new perspectives were introduced by Zowie Broach, Head of the Fashion Programme at RCA in 2016. The platforms, Bio Design, Sports, Digital and Future Systems were developed and led by Helen Steiner Graeme Raeburn, Kath McGee, and myself and supported by scientists, engineers, and digital technologists during students' first year at the RCA. The agile structuring of the

platforms has evolved year on year and the content is developed to be future facing and provocative. The groups are taught in parallel with an understanding that there are shared rationales, areas of interest and synergies. Collaborations across Platforms are encouraged. This work is supported by a lecture series and a Work in Progress show.

Each of the platforms has proved to be positioned in exactly the right place to respond to the Covid crisis. According to BoF-McKinsey State of Fashion 2021 Survey (2020), the most fertile ground for new opportunities will be in the areas of digital technologies and sustainability. The casualisation trend that was already in motion before the pandemic is likely to emerge as a ' dominant force' in fashion in 2021. By October 2020, sportswear company stocks had exceeded their pre-crisis-levels by 7 percent according to BoF, while the non-sportswear clothing was down 18 percent and designers are experimenting with a pre-order selling and zero stock models.

Strand 3, Fashion Thinking through Advanced Manufacturing is being further developed in the context of the FFF research investigating the potential for reshoring UK manufacturing in Industry 4.0. In order to equip masters' students with research skills for them to explore and critically examine Industry 4.0 it is proposed they will need both hard and soft skills. Skills that include an understanding of technologies, digital tools and engineering, married to critical thinking, collaboration and interdisciplinary working.

Vaughan (2017) claims that underpinning practitioner research is the understanding that the practitioner–researcher has the skills and expertise in the actions of the field to be able to undertake research within it. Citing Schon, Vaughan points to the transition from designer-practitioner to designer-practitioner–researcher in the course of academic study, as a shift from being able to understand and articulate the value or challenges of technical acts, to being able to place these in broader socio-cultural, technical and economic contexts.

Beyond Nixon and Blakely's notion of Fashion Thinking as "adding meaning and value to the functional and experiential spheres of products and services," (Nixon and Blakely 2012) that hints at the commercialisation of Fashion Thinking for use in business, just as criticism of Design Thinking proposed it as a branding exercise for a set of concepts (Curdale 2013, p 14) RCA research builds on the idea of Fashion Thinking as a "paradigm of critical thought and creative agency". However, rather than proposing Fashion Thinking as a methodology to be incorporated by organizations beyond fashion, its first function as a mixed methods approach to designer led research can be to serve a new generation of leaders *within* the fashion industry. Fashion Thinking as a methodology draws from perspectives developed in *Design Thinking*, Textile Thinking and STEAM +D approaches in its collaborative methods and iterative prototyping . However, RCA FFF researchers propose that through training at Masters level students can take on the complexity of the wicked problems the fashion industry has generated. This also aligns fashion thinking with parts of Transition Design. The *fashion thinker* will be better able to critically appraise complex situations and propose new approaches, systems and economic models through design. Led by, and in combination with, a newly developing confidence in practice based and practice led research, and inclusive of a

more traditional and well- established humanities/consumption focused research , I propose engagement with, and designing of, new technological advances can lead to a more environmentally conscious fashion and textiles industry. The possibility to foster this change is through joint industry/academic/ engineering engagement that is more investigative, critical and reflexive on both sides.

6. Discourse as provocation

Discourse: A Tool to Debate the Future of Fashion AS Design , designed by RCA Fashion graduate and Future Fashion Factory Research Associate Chelsea Franklin in 2018, was a card-based tool aimed at encouraging debate among fashion students on wider developments in education and industry and the scope of their responsibility. Franklin developed the tool over the course of two years with the support of Zowie Broach, the Future Systems Platform and the wider fashion team at RCA in response to her observation that the type of engagement seen in other design disciplines had not been fully represented in fashion education. Her background was as a designer for an international brand. *Student* engagement should, she proposed, include research around bottle necks in commercial opportunities ,an in-depth understanding of material choices, understanding global context, competition, and collaboration in industry 4.0. Her design research included investigating design tools and games such as those produced by IDEO. The aim of the initial prototype was a means for Franklin to illustrate her place and intention amongst the fashion cohort.

Discourse was created in response to a perceived disconnect between the value systems within fashion education and industry. Franklin suggested that the fashion system struggles to produce value. Responsible for both fuelling and exploiting a growing consumer demand for a faster and cheaper product, she believed the fashion industry had educated consumers to understand that fashion had very little value. The workshop developed through *Discourse* began with the objective of generating dialogue and supporting debate on aspects of the fashion system. This was tested by Franklin with her graduating cohort and at her degree show and then as an FFF researcher in two key settings. The first was the International Association of Societies of Design Research conference(IASDR 2019) in Manchester titled Design Revolutions. The workshops were premised on the idea that other design disciplines have much to teach fashion through open dialogue around shared problem spaces. It was observed that participants were able to engage with *Discourse* at a high level, and given levels of expertise in a range of fields, the responses were often delivered using examples from disciplines outside fashion as well as personal (consumer) experience and opinion.

The second workshop setting was at RCA in a series of workshops with first year and second year Fashion MA students. Though the aim was to encourage debate, analysis from data collected (sound recordings, survey-based feedback ,interviews) revealed that this was problematic for many participants due to lack of knowledge of specific industry terminology, conscious feelings of courteousness with peers and self-reported concern about ability to

understand the probing language of the questions. Although *Discourse* was designed to enable dialogue, interacting with it in a range of controlled settings revealed the wider challenges fashion students face in articulating and responding to the themes presented. Data collected from *Discourse* sessions with fashion students point to two major findings. Firstly, they appear to imply a lack of knowledge in certain aspects of the fashion system, in particular production and new technologies. Even if students had worked as designers, claims of being kept away from sites of production still persisted (Tham2008) Few if any students had worked in manufacturing settings. On the RCA fashion program, establishing means for language and skills acquisition through industry exposure, engaging in research projects as well as formal learning opportunities to develop meta- competencies aims to enable fashion students to critique, disrupt and innovate in the making, designing and fabrication processes, through and with the design of machines, new tools and systems.

Testing *Discourse* three sets of value were expressed: - students' value to industry, industry's value systems and consumers' understanding of the value of fashion. The findings show that students can sometimes feel ill equipped to tackle the complexities for the fashion industry. It is proposed that until students understand existing systems, they will be unable to challenge them and this becomes crucial for a post pandemic industry where returning to old ways is not possible or desirable. The absence of industry, engineering and science from fashion education can mean insufficient specific insights of the field graduates are about to enter. This is a historic problem in the UK which will see a dramatic change in fortunes in the coming years as the UK Government is faced with the new economic landscape facing fashion design. Meanwhile the reshoring the UK fashion industry looks like a more and more viable option.

Conclusion

The situation for Art and Design training at undergraduate and post graduate level in the UK remains complex and uncertain particularly in light of the UK 's withdrawal from the European Union. If the UK government continues to support the development of an advanced manufacturing sector and the reshoring of UK manufacturing industry then UK fashion education can rise to meet this challenge developing the way fashion is taught to engage more fully with Industry 4.0. At RCA the STEAM+D focus aims to give masters students a critical advantage, shifting towards becoming designer-practitioner-researchers. Through industry facing projects, collaboration with science and engineering they will able to engage more fully with industry partners both nationally and internationally, co-developing industry facing projects and placements, initiating collaborative industry PhD studentships and MA business sponsorship, and the establishment of research labs, co-situated within academia and commercial settings, to foster radical change. The development of fashion thinking is predicated on this engagement with industry. Within the context of post graduate fashion education, engineering and industry collaborations can enable acquisition of Discourse, where the role of the university will be to provide space for

learning - establishing meta knowledge, criticism and reflection through academic research channels.

Design culture of playing. The musical instrument industry: an important culture of made in Italy

Marco Mancini

University of Florence – DIDA Department of Architecture – DESIGNCAMPUS
m.mancini@unifi.it

Abstract | The production of musical instruments is an industry where Italy is one of the acknowledged world leaders.
A musical instrument is a product with a high degree of technology and design, where historical tradition and cultural roots have been handed down, together with the necessary incremental innovations: it has all the features to be considered a very "Made in Italy" product.
In any book, conference, exhibition about Italian design it can be easy to find many small traditional companies that produce furniture, accessories, bathrooms, kitchens, tiles, handles, shoes, clothes, glasses, food, wine, and cars: Ferrari is immediately identified as Made in Italy; on the contrary, it could be very hard to find excellent products as a Fazioli piano, a violin from Cremona, an accordion from Castelfidardo, a Harp from Cuneo, cymbals from Pistoia.
Why is the Italian musical industry still not present in the spotlight of Italian design?

KEYWORDS | MUSIC, MADE IN ITALY, PRODUCT, TECHNIQUE, TRADITION

1. Economic data

Some economic data can help to understand the importance of the Musical design industry in Italy: 1.021 enterprises are operating in the production of contemporary musical instruments with an export amount of 116 million euros (source: Registro Imprese and Istat, 2015). We are talking about micro and small enterprises and in some cases medium ones: 85% of active enterprises are of artisan production, 15% (144 enterprises) are industrial ones, with an average of 6 workers. Despite the dimension, the Italian musical instrument industry is important in international markets, and in some cases (Fazioli piano and other) it represents excellence. The export trend is increasing so that Italy is the 9th biggest exporter of musical instruments in the world. If we consider big countries like the USA and China and technological excellence like Japan, we can assume that it is a good position. Approximately 70% of Italian enterprises are located in 6 regions: Lombardy, Marche, Emilia Romagna, Veneto, Piedmont, and Trentino Alto Adige. This is mainly due to the deep connection between the artisan tradition, local materials, the history of music and the history of Italy in general. Districts and supply chains are fundamental in our musical production: some famous examples are the Recanati – Loreto – Castelfidardo district, with its keyboards and accordion (fisarmonica) production, the district of Cremona with one of the most important string instrument production, the North-Eastern part of Italy with its excellence in raw materials such as the red conifer of Val di Fiemme and Panaveggio forest (the one used by Stradivari for his violins). (Antoldi et al., 2016). It is curious that those 6 Regions with the highest concentration of musical industries also are the Italian Regions with the highest number of Design schools, universities, and academies. Many of the most important design congresses and exhibitions are held there, many times about “Made in Italy” but rarely about musical design.

2. Deep roots in the Italian culture

The contemporary “design made in Italy” has many opportunities in the field of musical production, starting from the very deep and ancient roots of the Italian musical culture.

The name which is currently in use for the seven notes was invented shortly after the year 1000 by Guido Monaco from Arezzo, by taking the initial syllables of a Latin ode to Saint John. During the following centuries, the study of music and acoustic phenomena from a mathematical point of view became a fundamental part in the work of great Italian thinkers like Leonardo and Galileo, who contributed to the birth of the scientific method. Moreover, until then, the basic education of the medieval scholar included Music in the Quadrivium, which is the area of mathematical disciplines (arithmetic, geometry, astronomy, music) and not in the Trivium of philosophical ones (grammar, rhetoric, dialectic). Music was science even prior to art.

In the 1700s, in Italy, the scientific aspect (related to study of acoustic and building of big theatres) and the artistic one (for example the great authors, musicians, and singers) were at a very high level. As a consequence, with the diffusion of opera and melodrama, not only the name of notes but also the standard reference lexicon of sheet music was in Italian, and it still is: dynamic *(pianissimo, piano, forte, fortissimo, …)*, pattern *(allegretto, andante, adagio, moderato, …),* and, more in general, all the words related to agogics, that is the interpretation of a music sheet.[1] Italian is known worldwide as the language of opera: to learn Italian is a fundamental step for any opera singer.

Therefore, the Italian musical cultural scenario, together with the Italian craftsmen's ability to build musical instruments, could be an invaluable source of supply for storytelling, input, and idea in the field of Made in Italy musical-related products.

Figure 1. Ancient violin arch tips – (Author: Anoixe)

3. Several records of Italian musical design

When the right scenario conditions are combined (culture, society, technology, economy), certain design products can trace the history of a specific market field, for example, the Ford Model T. By connecting many cultural, social, technological and economical inputs, it gave a strong push to the automotive industry and its spread and improvement. It was the right

1 Except some modern terms derived from black music, that are in English: Blues, Swing, Ballad, …

product at the right time, such as the Vespa Piaggio that characterized the Italian boom-years after the second world war. In a similar way, in Italy, the atmosphere of great concern and ferment about music, musicians, operas, songs, authors, performers, theatres provided the right conditions for the development of extraordinary inventions in musical design.

The inventor of the piano was the Italian Bartolomeo Cristofori (Edwards, 2015): by changing the existing harpsichord (clavicembalo) to allow a dynamic modulation of the sound, he invented his arpicembalo, then pianoforte (his first recognizable piano can be dated at 1720) at the end of a decennial research and development path that took him from his native Padova to the Florentine court of Medici. This extraordinary invention allowed the introduction of the possibility to play gently and loudly on the same instrument as opposed to the harpsichord, lack of dynamic expressivity. Even today, the key feature of the contemporary piano industry, in Italy and abroad, is the same concept of dynamic sound modulation proposed by Cristofori. To focus on the importance of the piano, it is crucial to consider that, among all the musical instruments, the piano is one of the most popular and widespread and in every school, it is propaedeutic to the learning of other instruments.

Figure 2. Double-action pianoforte built by Bartolomeo Cristofori in 1720; in the Metropolitan Museum of Art, New York City. Source: Encyclopædia Britannica - www.britannica.com/biography/Bartolomeo-Cristofori

Another fundamental Italian invention was the modern violin: the first preserved model, dated in 1564, was realized by Andrea Amati from Cremona. Starting from the 16th century in the triangle Cremona-Brescia-Venezia the lutherie art developed (Baroncini, 1994) whose construction techniques are still actual today.

The Italian input was fundamental in the development of another popular and diffused instrument, the guitar: the Neapolitan luthier families (Vinaccia, Fabbricatore, ...) started to release the first guitars with six single chords, instead of 'cori' (couples of chords) formerly used. Those gave origin to the modern concept of guitar (Ravalli, 2018).

4. Made in Italy: stories of territories, materials, and culture of technique.

4.1 Pure design

If we consider the perfect relationship between the function and the shape, between the engineering and the ergonomics, between the aesthetic value and the playability we can say a musical instrument is a pure design. Since many of them have an ancient history, they become archetypes in their use, sense, and meaning: this implies an optimization in their materials, technology, and usability. All the components must be optimized for a structural resistance or the transmission of the vibration, for this reason, industrial machinery is not always effective, often a manual working action is necessary: the typical sound of many acoustic musical instruments, especially the more complex ones, is due also to their production technique that, despite a company's industrial structure, still requires craftmanship expertise in many cases. (Mancini, 2019).

Design products, local materials, expert craftsmen, long-time tradition and attitude to innovation are important ingredient of what is called "Made in Italy" and, in the best tradition of "Made in Italy" products, the history of Italian musical instruments starts from craftsmen with fine technique deeply connected with the materials of their regions, where creativity and talent are important features, too.

4.2 The sound of materials

According to a study commissioned by CNA (Antoldi, et al., 2016), it appears that in Trento province there is a high export value (€ 8.66 million in 2015) due to enterprises that select, season and work the local red fir tree, a wood which is unique in the world for its sounding features, used in the production of soundboards and other resonance components of top-quality acoustic instruments. European, Asian, American luthiers are faithful purchasers of Val di Fiemme red fir (Picea Abies), known as "the music tree" or "the resonance tree", the same used by Stradivari for his unique violins. Today, about 60.000 luthier instruments, 15.000 harps and 180.000 pianos in the world are made with some of these components.

The strong export-asset and the excellence level are the main reasons for the success of these enterprises, which apparently don't know international crises.

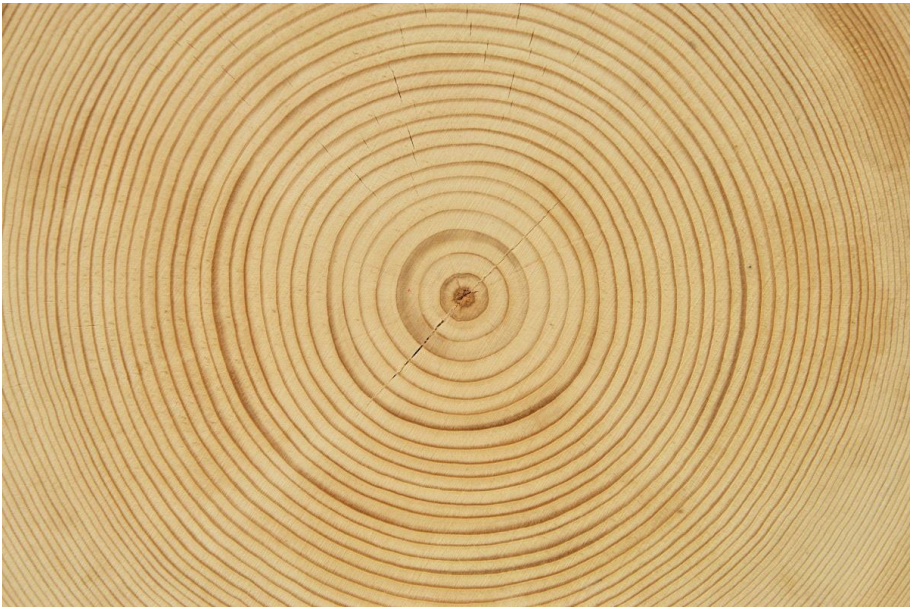

Figure 3. The perfect structure of a Trentino "Resonance Tree" – source: Archivio fotografico della Camera di Commercio I.A.A. di Trento (legnotrentino.it).

As often happens in the production of objects in many industrial sectors, local materials give the input for the birth of artifacts (i.e.: the alabaster of Volterra, the travertine of Rapolano, ...). Also, in the musical field, many instruments are built according to the natural sound of local materials: for example, in Budrio (Bologna), the local terracotta (pottery clay) is used to produce ocarinas, an ancient Italian wind instrument whose origins are lost in time, improved in the 800s by the local musician Giuseppe Donati who started the "modern era" of ocarina production, for which Budrio is famous.

4.3 Materials and manufacturing

Many histories of design products are related to the ability of craftsmen to work a specific material, derived from a long-time technical tradition: i.e., the ability to work the leather and the famous made in Italy shoe enterprises. In the musical industry, an important Italian tradition is derived from the millenary art of metalwork. In Agnone (Isernia), the *Pontificia Fonderia* (exclusive pontifical foundry since 1924) *Marinelli Snc* has a long tradition in bells

production (on the factory website they say about 1000 years of tradition) and today is famous worldwide in this specific production field.

Figure 4. UFIP – Est 1931 series cymbals. Courtesy UFIP – Pistoia, Italy

Another common feature of many Italian enterprises is the small dimension. Sometimes factories are family-owned as is the case of Pistoia, where in the 18th century the family enterprises able to work metal started to build church organs. Then the ability in the lamination processes was successfully applied to the production of cymbals. During an economic crisis, in 1931 four of these small enterprises decided to join, establishing the *Unione Fabbricanti Italiani di Piatti musicali e tam tam* (Italian cymbals and tam-tam united factories), called UFIP. The deep connection with its origin, that is the ability to work metal, led UFIP to innovate the cymbals production by patenting the *Rotocasting®*, a unique centrifugal casting system that allows the elimination of all the impurities of the bronze alloy. Today UFIP is known worldwide for the top quality of its cymbals, an Italian made in Italy excellence of design.

4.4 Manufacturing and culture

The knowledge of a working process can be another important factor in the development of a specific industry, on a regional basis, as it happens in many industrial districts (as Udine and its production of chairs, Florence and its leather products, …). In the musical field, the case study of accordion could be representative. The accordion is an instrument that was not invented in Italy and that is not necessarily built with local materials. The accordion probably was first built in Austria and from the mid-XIXth century was diffused in Italy, in the Marche region, above all by the work of Paolo Soprani. Today a great part of Italian popular musical culture is based on songs and rhythmic patterns played on the accordion. Especially in summer, there is no local festival (*Sagra*) without an accordion player in the live band. In the

Tuscan countryside until the 80s, the accordion could often be identified as “the” musical culture. This extraordinary diffusion, in Italy, of an instrument which is not native Italian (for materials or birth), was due above all to the great ability of Italian craftsmen: in 1924 93 accordion factories in the national territory were recorded. Today the most famous are produced in Marche (Castelfidardo and Macerata), Lombardy (Stradella, Cremona), Piedmont (Vercelli, Leini) and Tuscany.

As before reported about UFIP, an economic crisis was the occasion for a union of different factories: in 1946 the *Fabbriche riunite di fisarmoniche* (united accordion factories) was created, with the name FARFISA, an excellent company whose experience was based on the production of keyboard instruments (accordion, keyboards, electric organs, …). It started the development of the Italian most important musical production district - the Marche district. A famous FARFISA product was the Compact, one of the first electric organ produced on an industrial basis, widely diffused in the 60s and co-responsible (together with the Vox Continental) of the sound of the rock and psychedelic music of those years. An electric organ is an instrument based on a simple concept: the pressure applied to a key generates a sound through electro-mechanical internal components. It is the same concept of an intercom: by taking advantage to its achieved know-how, today Farfisa is an internationally known company that produces intercom and videophone all over the world. Another story of made in Italy.

Figure 5. Navini accordion. Courtesy G. Navini snc – Castiglion Fiorentino (AR), Italy

Differently from other product categories, where industry replaces small artisan factories, in the musical field, this substitution is rarely possible because the quality of certain components can be guaranteed only by manual work. Moreover, a big industry is not often able to provide the possibility of fixing damaged instruments. This particular attitude of Italian small enterprises is important because in music there is no programmed or forced obsolescence as in other industrial sectors: a good instrument is expected to last for decades, so the maintenance service is still fundamental. This is both the reason of excellence of Italian musical instruments and the reason why small familiar companies still survive, as G. Navini snc, established in Tuscany in 1936 (Castiglion Fiorentino), which still today is a reference point for accordions and maintenance service for many musical instruments.

4.5 Highly skilled enterprises and craftsmen

Many small enterprises in Italy are famous for their musical instruments, thanks to the extraordinary ability of their craftsmen.

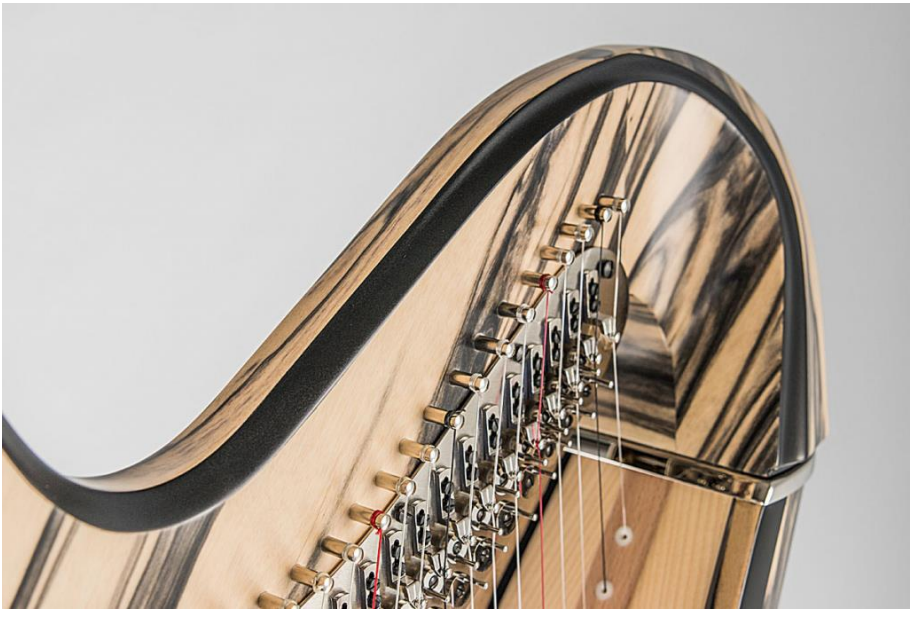

Figure 6. Salvi harp – model Whitney, with white ebony veneer. Courtesy Salvi Harps – Piasco (CN), Italy

Salvi harps is one of the most important harp producers in the world. Since the first appearance of a harp in an orchestra, thanks to the Italian composer Monteverdi (in the first year of XVIIth century), the harp and its soundboard had to adapt the volume to the

increasing dimensions of orchestras and auditoriums: for this reason, the research for materials with the best resonance features was fundamental, together with the study of optimal shape for the sound boards. The use of the best resonance material (the red fir of Val di Fiemme, used as the main component of the soundboard) and the continuous search for innovation (the company has its R&D department inside) are some of the reasons why this company ubicated in Piasco (CN) exports its instruments worldwide. Its long tradition, started in the mid of the XIXth century, permitted them to train generations of artisans: today the high expertise of the workers makes the difference and Salvi can be considered as an excellent Italian company.

Rampone & Cazzani is an Italian company ubicated in Quarna Sotto (VB) that has produced saxophones since the invention of the instrument (by Adolph Sax in the second half of XIXth century). Today it is considered a niche market manufacturer, thanks to the great sound of its instruments, the perfection of details, the possibility of customization.

Figure 7. Rampone & Cazzani – model R1 jazz. Courtesy Rampone & Cazzani – Quarna (VB), Italy

5. Fazioli, a made in Italy brand of excellence

In New York, in September 2003, during the celebration for the victims of twin towers destruction, a concert for 21 grand-pianos was played: they were Fazioli pianos; at the White

House, in 2016, during the celebration for the International Jazz Day, Aretha Franklin and other international stars played a Fazioli grand-piano (AGI, 2016). Fazioli is an Italian piano factory whose concert grand-pianos are famous worldwide and appreciated by many important pianists. The company was established in Sacile (Pordenone) nearly 40 years ago, from a spin-off of the main family factory, a wood working factory, and since then it shuns the production derived from an industrial nature but, on the contrary, it pursues a strategy that combines an absolute technical perfection – derived from in-depth studies of materials and sound engineering – with a traditional handicraft production. These factors combined with the choice of the best woods from the Val di Fiemme trees are the carriers of technological innovation and absolute quality. In a Fazioli piano, there are several patents: the exclusive three-layered soundboard, the unique fourth pedal, but beyond these innovations what matters is its recognizable sound, a strong brand value. The annual production is of about 140 pieces, 95% of which are exported all over the world: they are the numbers of a small company of excellence if we compare it with the biggest piano factory in the world, the Chinese Pearl River that produces 150.000 piano/year (Stefanato, 2018). The choice of the founder (Paolo Fazioli) was to create a high-level object with a special focus on a contemporary Italian sound that was different from the other famous brand (Steinway, Yamaha, …).

Today we can say that, if Fazioli is called the “Ferrari of pianos”, this ambitious goal was achieved (it is curious to notice that, similar to a car, a piano is a mechanical engineering product): many great pianists like Herbie Hancock or Angela Hewitt, in some interviews declared that they prefered Fazioli grand pianos instead of Steinway for their concerts.

6. The districts of the Italian musical production

In the field of design, the concepts of districts and supply chains are well studied. Even in the musical field the same features applicable to the definition of a district can be found: when companies use local materials, when they share competences, when they optimize their know-how, when they create a network for promotion and marketing, in these cases real sites of production born and music-related industries can develop. In Italy, two districts of musical production can be identified: Cremona and the Marche district.

In Cremona, the roots of the art of lutherie can be dated in the XVIth century with the products of the Amati family. Then, in the golden era of Italian music, the XVIIth century, Guarneri and Stradivari defined the archetype of arch instruments, today still in use worldwide. People in Cremona were able to take advantage of this long tradition of made in Italy, through structured actions regarding both the enhancement of existing asset (material and immaterial) and the promotion of “new”; actually in Cremona we can find: the Stradivari foundation, the international lutherie competition, the international lutherie school “A. Stradivari”, the Superior Institute of musical study “C. Monteverdi” and the academy “W. Stauffer”, the violinmakers and archmakers (liutai & archettai) consortium “A. Stradivari”, the international exhibition Cremona Mondomusica with more than 300 exhibitors per year[2], the innovative Violin museum, the “Laboratory of musical acoustics” by Politecnico of Milan, the Arvedi laboratory for non-invasive diagnostic analysis of University of Pavia. A strong component of innovation is the key to the enhancement of tradition. The institution of the “Cremona Liuteria” trademark based on a specific production regulation was set up to prevent industrial standardization and to preserve and guarantee the Cremonese musical instruments[3]. In 2012 the “traditional violin know-how in Cremona” was declared Intangible Cultural Heritage by UNESCO. The result of this organic approach is a strong growth in the sales, above all in exports: in 2015 the export of musical instruments in Cremona was € 4.225.170,00, + 11,85% as compared to 2014, +553,23% as compared to 1995; those data demonstrates that the excellence market is still able to grow, despite international crises, even because it doesn’t follow temporary trends. An interesting fact is also that 42% of the total of 154 luthier artisan workshops have a foreign owner: the attractiveness of Cremona is very high especially outside Italy, not only towards students but also towards entrepreneurs (Antoldi, et al., 2016).

[2] http://www.cremonamusica.com/en/

[3] http://www.cremonaviolins.com/il-consorzio/il-marchio-il-regolamento-la-tutela/

The Marche musical district is the biggest area of musical production in Italy, with the highest value of turnover. While in Cremona the district is connected with the specific production of arch instruments and its related technologies, in Marche the district is hybrid and not focused on a specific kind of instrument. All started with the production of accordions (see above about FARFISA), an instrument with keys where the sound is generated by a blower; during the following years the local factories could adapt to new technologies and the market changes: by electrifying the harmonium (where keys and blower are the same components of the accordion) in the 60s the electric organ was introduced, then the first keyboards (electric piano) were produced together with the first Italian electric guitars (Eko). Today many fields of music production are active in the Marche district: keyboards, electronics, amplifiers, speakers, … and many international industries such as Korg and Roland take advantage of the ability of local craftsmen and factories. Today Eko Music Group Spa, Fatar Srl, Korg Italy Spa are some of the enterprises with the highest turnover (ICRIBIS, 2020).

7. Some opportunities

The word design is paired with the word music in a very few cases, most of them referred to home acoustic speakers that are considered pieces of furniture to be put in a living room or in a bedroom: in this specific field, the good design seems to be considered a value for the product and is also used for advertising campaigns.
Among the musical instruments producers, few companies consider design as an essential feature of their products (on the contrary, in other market fields, in certain products the word design is shouted and exhibited, sometimes out of proportion, sometimes without any good reason). In musical instruments, Design seems to be an additional feature, that comes after all the main product qualities: tradition, materials, sound, prestige. Even amongst the companies mentioned in this paper, it is hard to find the word design in any of their websites. In the academic world, some books regarding design and music can be found (i.e. in Italy the recent book of Marano, 2019), but they are far too few to be considered as effective literature on the topic.
Another area with a lack of design-driven attention is the world of exhibitions or expo. In big design events as Salone del Mobile in Milan or 100% Design, visitors are not only operators, sellers, designers or entrepreneurs: a large part of public is made of curious people or people not directly involved in the topic of the expo; in those big fairs, however, musical products can rarely be found. In music fairs it is just the opposite, that is only a few are curious people amidst the majority of insiders.

Deep cultural roots, long-time tradition, fine materials, excellent craftsmanship, brand value, product durability, attention to innovation: many Italian musical industries possess all of the qualities usually related with the Made in Italy, a heritage that could represent a real opportunity to open new roads in the wide meanings of design.

Design related to musical instruments and accessories could be the topic for research projects, academic courses, workshops, conferences, fairs, and papers. Designers, professors, and students could be involved in this specific field and, for example, producing a structured survey of the Italian musical industries: each one of the factories, just mentioned in this paper, would deserve a wider discussion for the wealth of their technical know-how, their ability to work local materials, the durability of their products.

Italy always expresses high cultural value in music, both at an international level and at local and regional ones; this is another point of view to start from, for an inclusive approach to music design and its preserves.

Digital encounters in the culture of textile making: developing a hybrid craftmanship for textile design by fusing additive methods of surface fabrication with knitting technology

Delia Dumitrescu

The Swedish School of Textiles, University of Borås, Sweden
delia.dumitrescu@hb.se

Abstract | Digital fabrication technology presents an unfamiliar territory for textile design, thus requiring exploration and analysis of the emergent forms of textile crafting and materiality. Through practice-based research methodology, this research examines the intersection of two fabrication methods: industrial knitting and 3D filament printing, with the aim of outlining a hybrid material territory for 3D textile composites. Accordingly, the research addresses the notion of textile as a multi-material system. The physical results are presented as a material library of samples which have been produced through two methods: i) the exploration of geometric tessellations to generate self-folding surfaces by direct printing on non-elastic knitted structures; ii) the exploration of pattern arrays to generate self-forming surfaces by direct printing on pre-stressed knitted structures. Using this hybrid approach to textile crafting the research discusses the aesthetic possibilities of the fusion of these two technologies, and the potential for development within the Industry 4.0 model.

KEYWORDS | TEXTILE DESIGN, HYBRID METHODS, MULTI-MATERIAL SYSTEMS

1. Introduction: textiles as culture of crafting

Being one of the few disciplines which has the material–the textile–as the resulting artefact of the design process, textile design complies with Risatti's definition as a culture of crafting: one that is based on advanced technical knowledge and direct experience of the material in the creative process. Based on Pye's distinction between the two notions of design and workmanship, the concept of craftsmanship emerges in Risatti's definition as a unifying activity of the two rather than a separating one (Pye, 1968; Risatti, 2009). In this context the notion of crafting combines in its description the intellectual and creative nature of design activity, together with the proficiency of technique and material knowledge which is conveyed by the attributes of workmanship. Likewise, crafting as activity implies an integrated process between artistic expression, design, ideation, material and technical knowledge.

Consequently, artistic expression and technical proficiency are closely interrelated in the practice of textile design, as the culture of crafting and materialization have always been deeply rooted within it, even though the rise of industrialization has triggered major challenges for the textile design field by separating the designer from workmanship in the production process(Gale and Kaur, 2002). However, the value of craftsmanship and making through direct interaction with the textile has been preserved(Valentine et al., 2017). Likewise, knowledge of the material, together with the process of forming and making, define fundamental placeholders in the development of an intended design and desired textile quality. Another aspect resulting from the legacy of the culture of craftsmanship is that the development of technology and methods of making textiles are driven by the experience of the material as key to the design process, which then influences ways of creating expression in textile design(Ingold, 2009). Pye defines this process as "the workmanship at risk", where the designer's methods are not fully known, leaving a place for exploration and redefinition of the known technology by experience.

Today, the extended availability of digital tools and methods of fabrication have unlocked new design possibilities for the expression of textiles which rely on established textile techniques, e.g. weaving, knitting, screen-printing. In particular, the extended availability of 3D printing technology marks a complex material turn for the textile field (Smelik, 2018). Likewise, McCullough(2010) discusses the role of the digital tools in the design and crafting process; the digital has opened a hybrid territory of abstract forms of materiality which make the transition between tactile to haptic processes, and requires the development of novel forms of crafting.

Digitalization, in addition to enabling these novel material practices, has also influenced the development of new production processes and new models for co-locating industries: with reduced scale but with mixed competences and fabrication lines–Industry 4.0 (Lasi et al., 2014). Manzini envisioned this change of industrial models in the book The Material of Invention, published before the present turn to the digital in material and fabrication technologies:

> "The boundaries between privileged sectors tend to break down. What it comes into being is the formative nucleus of a situation in which the vertical model is replaced by a model in which relations are established, as they are needed between manufacturers in the various fields with a view to a specific objective-to develop and market a new, partially processed composite or else to manufacture a finished object, created by multimaterial components." (Manzini, 1986, p.43)

Hence, this territory is no longer defined by traditional technologies or mono-component identities; it is defined by cross-disciplinary practices and methods which stretch the borders of different design disciplines by fusing traditional and unconventional forms of making, e.g. shape-generative processes, composite materials, and novel fabrication methods, enabling the transition from bottom up to relational processes for the creation of textile artefacts.

2. On novel processes and hybrid craftmanship in textile design

Similarly to specific material classes such as wood, glass, and steel, textiles form their own class. The fusion of textiles with other materials requires a new classification for the multi-material created. Conventionally, the term "composites", however, introduces a mixed methodology and describes a broader cluster of materials which are formed through the fusion of different material identities and properties (Fernandez, 2006). Consequently, for the textile field, the term "textile composites" refers to a specific class of materials where the technology to fabricate them "implies fibre and resin matrix structures built from material laid up on a mold, and thermo-formed under heat and pressure." (Pearson, 2016, pp.305). Here the characteristics of textiles, such as pliability, lightness, and structural integrity, are mixed with the stiff character of resin. The casting and molding process is employed to enable the creation of textile composites with stable surface behavior and which can exhibit stiffness and three-dimensional shape (Bonder et al., 2019).

Compared to the conventional method of molding when creating textile composites, the use of 3D filament printing technology as an additive method for altering textile surfaces introduces another perspective. This method presents a hybrid space for creating textile composites which places itself at the intersection of known methods of textile composites– by mixing textile structures with polymers–and traditional 2D screen-printing methods. The pliability of the textile is mixed with the geometry and rigid behavior of the additive printed pattern, enabling surface shaping capabilities. This intersection of two material domains underlines a hybrid territory where 3D shaping, material behavior, textile construction and 2D surface pattern design meet to define a composite material system comprised of two distinct material identities: textiles and plastic polymers.

This cross-disciplinary textile territory is illustrated by the research and design of Van Herpen (c.f. Thys, and Connellan, 2012): her work with additive processes defines new perspectives on material agency and positions the notion dress as an architectural form for the body.

Clopath and Guberan, researchers at MIT, have proposed another perspective on 3D printing by combining this technology with textiles in a shoe that adapts to the wearer's patterns of movement (Active Shoe, 2020). Likewise, Moslemian(2016) further explores the principles of self-folding when 3D filament printing technology is applied on textile to design active textiles. By proposing and analysing different geometries her research presents methods to work with these hybrid materials in an architectural context, with the aim of designing light-weight structures.

Many other research examples that combine textiles and 3D printing come from the field of textile engineering, and examine the technical aspects of this combination, for example material bonding and interaction, or smart properties (Pei & al., 2015; Grimmelsmann & al., 2017). Consequently, the ubiquity of and increased interest in 3D printing technologies has resulted in expressive fabrics that present a visually attractive textile that is unfamiliar to us in its crafting. Here, the intricate geometry of shape and the combination of hard and soft material properties fuse attributes of the generative expression of form with the properties of the printed material and the qualities of the textile. The exemplary research discussed above outlines the research context by demonstrating different perspectives as to how these hybrid methods of multi-material systems can be approached through crafting design and technology. However, in most of these examples, textile base is used as background for the printing technology rather than foreground, thereby leaving an open question as to how the textile craftsmanship can be leveraged to a better advantage in this intersection of technologies. Subsequently, this research looks at the fusion between knitting technology and 3D filament printing, starting from the making of the textile structure in a bottom-up perspective of the knitted structure.

Using a practice-led research methodology, this research analyses the textile design possibilities resulting from the fusion of two methods of crafting and making: digital fabrication and knitting technology. What is crucial to this research is: i) to exemplify a hybrid method of designing textures and self-folding forms in knitting, and thus go beyond the current limitations of this textile technique with the help of digital fabrication; ii) to articulate a design vocabulary describing the textile qualities resulting from the fusion of the two techniques, and the advantages of doing so in terms of combining the properties of two distinct cultures of making–digital and textile fabrication–as a means of suggesting new possibilities for material design and to broaden perspectives on form-thinking in the textile design process.

3. Fusing methods

Knitting as a textile technique was primarily developed to enclose the body. In knitting the loop is the fundamental unit of construction(Black, 2012). Therefore, loop geometry, multiplication and arrangements decide the end design of the knitted surface and the geometry of the 3d shapes. Similarly to other textile construction techniques, in knitting

there are two perspectives that interact in the design process of a material: the microscale (near-field), which is defined by the construction unit and yarn dimensions; and macroscale (far-field), defined by the design of the overall surface and shape. Alongside the process of creating complex shapes, the character of the yarn as raw material for design, and the structural design, are equally as important in the process. These two elements determine the aesthetic and functional properties of the surface: the feel of the surface against the skin, the outline of the shape, and the folding behavior in relation to the body. The construction techniques specific for knitting allow designers to work with both the 2D surface and 3D shaping (Glazzard and Breedon, 2012).Compared to other textile structural techniques, the fundamental properties of knitted textiles are elasticity, pliability and self-folding. Thus, 3D printing as a fabrication technology introduces the opposite elements to knitting into the textile design process: working with 3D solid objects with contrasting qualities to textiles–stiffness, transparency, smooth surfaces–and crafting in a non-physical process. The result of joining together the two technologies proposes a series of textiles as a multi-material system(Grimmelsmann et al., 2017).

Similarly to textile yarns, there is a large variety of 3D printing filaments which vary in terms of materials, colors and stiffness, e.g. PLA, ABS, Nylon. These filaments may also vary from soft to hard. However, in this research the interest was to fuse textiles and 3D filament printing variables with contrasting properties in order to be able to generate a composite material system situated at the intersection of the two fields, and therefore [hard/stiff] filaments were used.

The experiments explored various possibilities for generating three-dimensional surfaces when the pliability of the knit is forced into shape by the rigidity of the 3D printed layer. Two strategies have been employed: the principle of self-folding by 3D printing geometric tessellations on non-elastic surfaces; and the principle of self-forming by 3D printing on elastic surfaces. Figure 1 presents a material library with selected expressions resulting from the fusion between the two technologies.

2.1 Material Set-up

The knitted textiles were fabricated using circular single-bed (gauge 12) and flat-bed (gauge 14) industrial knitting machines using simple typologies: for example, on the single-bed machine single jersey, three-thread fleece knitted fabric, and meshes, and on the double-bed machine 1x1 rib structures. These structure types provided a greater degree of control over the stretch directions of the fabric and ensured equal distribution of tension on the textile surfaces. The quality of the surface of the additive layer was also dependent on the uniformity of the textile surface, as a high level of variation would obstruct the smooth movement of the 3D printer's nozzle, damaging the fabric. In order to be able to add colors and patterns to the textile surfaces without influencing the geometry of the knitted base, two plating methods were used. In order for the circular knitted textiles to have two distinct faces, yarns with different colors were knitted simultaneously on the front and rear of the

fabric. For the weft-knitted textiles, the colors were added as patterns on the front, and randomly mixed on the rear; this was achieved using the programming environment of the Stoll machine, which uses a color-arrangement system that allows simultaneous work with color, pattern, and structure using plating technology. The fabrics used for the final experiments were knitted using natural fibres, e.g. cotton, viscose and wool, along with elastane. The choice of yarns was the result of the intention to create a contrasting expression between the textile base and the printed filament. Previous experiments showed that these materials have the best adhesion to 3D-printed filaments, and that they do not melt when the hot extruder comes into direct contact with the textile surface.

With regard to the exploration of the variables of the 3D-printed layer, filaments made of different materials were tested as additive layers on the knit, e.g. PLA, ABS, and nylon. However, ABS, PLA and nylon were considered to have the best adhesion to the knitted fabrics and the best bending behavior with regard to the explorations of self-forming behavior. Previous experimentation showed that the thickness of the printing layer, along with the character of the filament used, influences the attributes and behavior of the additive pattern. The height of the 3D-printed layer is dependent on the size of the printed area and the outline of the two-dimensional pattern to be applied to the textiles. The experiments were undertaken using a 3D printer with a printing area of 220 x 220 mm. For the explorations of self-forming behavior the thickness of the printed layer was 1.5 mm; for the explorations of self-folding behavior the thickness of the printed layer was 2 mm.

2.2 Strategies for three-dimensional forming

The physical results of this research are a material library of samples, which were explored using two methods:

i. Geometrical tessellations that resulted in self-folding surfaces as a result of 3D printing directly on non-elastic knitted structures.

ii. Pattern arrays that resulted in self-forming surfaces as a result of direct printing on pre-stressed knitted structures.

Figure 1. Samples that explored the self-folding behavior of three-dimensional prints on knitted objects.

i. The first method involved the creation of different geometries with self-folding behavior through 3D printing on knitted structures. The self-folding behavior of the surfaces was not dependent on the elastic property of the surface; this type of pattern can be applied to non-elastic surfaces as well. The self-folding expression of the 3D-printed textiles was dependent on the relationship between the 3D-printed facets and the textile creases (Saito et al., 2015). During the drawing of the pattern to be 3D-printed, the initial mesh was split into individual elements. Each cell was offset by 3 mm from the neighbouring cells, allowing the formation of creases on the textile surface after the fabrication process, and the cells as a whole constituted the surface of the textile.

Samples 2, 3 and 4 (Fig. 1) illustrate the design of quadrilateral meshes composed of regular and irregular cells. Sample 2 and 4 have a regular pattern. The pattern of Sample 2 was printed with a thermochromic filament which changed from green to yellow. Due to the plating methods used in the knitting process, the color of the textile base varied from green to beige to yellow. The sample was intended to explore how the three-dimensional perception of a surface could be enhanced when working with tone-on-tone using color combinations (Fig. 2).

Figures 2 and 3. The three-dimensional forming potential of Samples 2 and 1, respectively.

Sample 3 was 3D-printed with an irregular quadrilateral mesh which restricted its self-folding behavior as compared to Sample 2. The printed mesh had a discrete expression due to the use of a transparent nylon filament. The folds of the surface were emphasised due to the textile substrate, which was knitted with a three-tread fleece pattern. The 3D-printed facets of the quadrilateral mesh of Sample 1 were narrow and high. The pattern was printed on a pre-stretched fabric (single jersey, gauge 12, cotton and elastane). When the textile was released from the printing bed, the filament formed a dense structure which maintained the softness of the textile; although the expression of the textile was two-dimensional, the surface was possible to shape in three dimensions by twisting the two ends in opposing directions (Fig. 3). Samples 5 and 6 illustrated ways of folding using the method of aligned curves (Mitani, 2019); this method facilitated the creation of less structured geometries with softer edges and smooth gradation of the sizes of the three-dimensional printed patterns. As compared to Sample 6, wherein the knitted textile is rather neutral being a single jersey fabric which was plated using a light blue front and white rear, the textile of Sample 5 merges in the foreground of the expression with the 3D-printed layer adding color and texture to the end design.

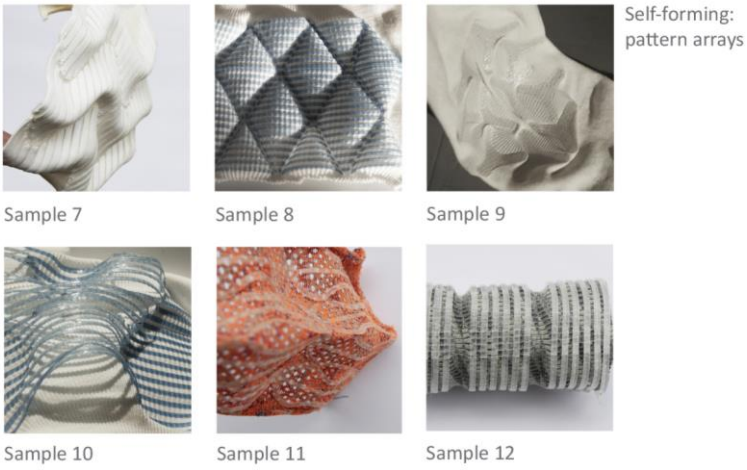

Figure 4. Samples that explored the self-forming behavior of three-dimensional prints on knitted objects.

ii. The second method explored the potential of 3D-printing primary shapes, e.g. lines, squares, circles, and triangles, with the aim of creating three-dimensional self-forming fabrics. The edges of primary shapes printed on textiles have the potential to bend due to the tension of the textile surface; this method thus facilitated the creation of various curved three-dimensional shapes (Aldinger et al. 2018; Moslemian, 2016). Consequently, a good understanding of the bending behavior of primary shapes on pre-tensioned knitted structures would be a great support for the ways of working in textile design, as the simplicity of the 3D-printed pattern would allow for more freedom for the actual design of the textile base. Samples 7 and 8(Fig. 4) show the effect produced by the alignment of fine 3D-printed lines on a fabric which is stretched in both directions. Sample 7 used a single-jersey fabric as a support material for the 3D-printed pattern. The fabric exhibited uniform elasticity because every row was knitted with elastic yarn and wool. The fabric was stretched in both directions, but more in one direction. When steamed, the flat fabric compressed more in one direction, causing the 3D-printed pattern lines to curve. The lines of the 3D-printed pattern became closer in the other direction, emphasising the regular folds of the emerging texture. In the image of Sample 8 shown in Figure 4, the 1x1 rib structure was stretched during the 3D-printing process such that the 3D-printed lines curved the diamond pattern. The lines of the 3D-printed pattern thus interacted with those of the pre-stretched rib forming an unified expression.

Sample 9 explored another way of forming a dome-like shape; by designing an array of triangular units that were printed on a fabric that was stretched in two directions. In this example, the complex outline of the 3D-printed shapes formed the elements of the textile surface design by distorting the lines of the fabric. The textile fabric of Sample 11 combined

an advanced textile design defined by variables, such as pattern, color and structure, and an array of curved shapes which changed the surface expression. As compared to Samples 7 and 8, wherein the design of the print comprised the foreground of the textile expression, the 3D-printed layer of Sample 11 became a background in the overall expression due to the design of the textile. Samples 10 and 12 utilised a method of partially printing the filament on the textile. In both examples, a secondary layer of three-dimensional patterns emerged due to the fact that the filament was partially attached to the knitted fabric. Whereas in Sample 10 the filament constituted the foreground of the textile expression due to its textured shape and color, in Sample 12 the three-dimensional print merged into the surface design of the textile. This textile was knitted using a 1x1 rib technique, onto which an abstract surface pattern was applied using plating.

4. Discussion

The result of this research presents a strategy for designing textile multi-material systems for 3-dimensional surface design when combining 3D filament printing as an additive technique with knitting technology. Accordingly, the research presents two methods: i. the first method uses patterns of geometric tessellations to generate self-folding surfaces by direct printing on non-elastic knitted textiles; ii. the second method uses geometric pattern arrays to generate self-forming surfaces by direct printing on pre-stressed knitted textiles. The material library illustrates some of the variety of expressions and surface behaviors that can be achieved with this fusion of technologies.

Similar 3D textural effects in textiles can also be achieved through conventional screen-printing methods, using materials such as flocking or printing foil, as the exemplary research of Philpott (2012) illustrates. However, the great advantage of using 3D filament printing is the robustness of the additive material on textile which allows the formation of 3D shapes without limitations of the layer's thickness and scale. The effect of the character of the printed material–the transparency, translucency or smoothness of the plastic layer–gives the textile materials, e.g. wool or cotton, a hybrid tactility, altering the conventional textile expression. The pattern generation work in the digital space introduces a new form of textile crafting since it goes outside established 2D textile methods to create pattern repetitions–while being influenced by traditional textile craft techniques. Based on haptic processes, the digital space enables extended possibilities when working with complex 3D typologies and for enhancing the perception of depth of the 3D surface by manipulating directly the pattern design on it.

By fusing contrasting material behaviors and merging two distinct technologies, the proposed method exemplifies an alternative way of approaching the design of complex knitted constructions with the aim of achieving post-fabrication formation of 3D textures and shapes. The method places itself at the intersection of textile technology and digital fabrication, outlining an alternative method for designing and fabricating textile multi-

material systems which may open new material functionalities and extend the limits of textile design and crafting. This hybrid method relates to the perspective of textile as a multi-material system, defined by changeable variables which can be modified according to the function of the material in the object design process, rather than producing a unique textile design. It is a textile system in which the digital–characterized by extended possibilities to create 3D patterns and arrays–is merged with knitting technology in order to re-design the materiality of the knit as a foundation for the design. If so far the role of the material in the process of object-oriented design disciplines, such as fashion, product design or architecture, has been described using linear models of design, e.g. bottom up or top down, the notion of textile as multi-material system relates to Manzini's description as a "model of relations" or to Frayling's(2011) New Bauhaus as model of "convergence" might introduce an alternative perspective of a distinct nature from the previous ones; this perspective can be defined by flexible boundaries capable of extending the synclastic model of design(c.f. Ingold, 2009) to the object-oriented design disciplines–where the material and object define each other in the design process.

Nowadays, due to a high interest in developing sustainable processes and products, the structure and premises of the current industrial model are highly debated. The advanced digitalization of fabrication tools and methods of communication are driving the textile industry towards a new era: that of Industry 4.0, where product design and manufacturing processes are not separated but become co-located, alongside the different disciplines engaged in the process. The total re-definition of the industrial model also enables a re-positioning of material in the product design process, towards finding new forms of craftsmanship inside the established methods of each design discipline. Although Industry 4.0 is a relatively new concept, it presents novel possibilities for the role of material in design processes and an opportunity for textile designers to work closer to technology and fabrication, where textile digital crafting proficiency will be most beneficial.

[a]Department of Design - Politecnico di Milano
patrizia.bolzan@polimi.it

Abstract | The paper investigates the role of distributed design and digital fabrication in the materialization of open source healthcare solutions co-developed by designers, makers, and user innovators with or within enabling environments such as makerspaces. A participatory and experimental design-oriented approach allows to refine the nonlinear development path that characterizes new fields in which design, technological experimentation and medical research may find application possibilities can also be identified. With these premises, this work aims to explore the dynamics of designing products related to the emerging field of Distributed Care. Firstly, the paper defines the emerging field of distributed design for healthcare and analyses experimental initiatives exemplifying the field of Distributed Care. The second part of the paper interprets the results of the use case analysis to demonstrate how designers, makers and independent innovators interacting with care specialists, patients and caregivers – can design, produce and distribute solutions with a real market potential.

KEYWORDS | DISTRIBUTED DESIGN, DIGITAL FABRICATION, MAKING, OPEN SOURCE HEALTHCARE, FAB LAB

1. Designing (for) distributed systems: an introduction

Nowadays, terms such as "distribution" and "distributed systems" have become a common, constituent and characterizing part of the production, release and diffusion models of many goods and services on the market. *Blockchain*, *cloud computing* and *manufacturing* are examples of distributed technologies. It was not until the early 2000s that the theme of distributed systems crossed the discipline of design. The scientific literature on the design of distributed systems mainly refers to the world of computer science and in particular to the design of computer systems (software engineering). We speak of distributed systems design or distributed computing environment to define a system whose components are located in different networked objects (e.g. computers). These components act in a coordinated way by sharing information to achieve a common goal. A distributed system is basically a set of independent processors that enable the sharing of resources through the use of software and allows the system components to operate autonomously, independently and geographically spread. The distributed systems are characterized by certain properties: *transparency* in the access and use of its resources, *openness* that facilitates the configuration and modification of the system, greater flexibility and interoperability, reliability in the resolution of errors and problems, and the ability to concentrate performance capacity and to scale physically, geographically, organizationally (Wu, 1999).

Another strand of scientific literature on distributed systems comes from the world of industrial engineering and management, more specifically related to the concept of *distributed manufacturing* (Marsh, 2012; Künhle, 2010). Basically, distributed production is a decentralized and networked model to organize local manufacturing processes. Digital transformation, especially the development of digital fabrication, has empowered this model and its operability. Organisations and individuals (professional, citizen, and *indie* innovators) can use a network of production facilities and technologies geographically dispersed but connected and coordinated through ICT technologies (Seravalli, 2013; Wolf et al., 2014). The spread and the convergence of a growing number of small-scale production activities, which are fuelled by a plurality of subjects and organizations and characterized by a democratized access and use of manufacturing resources, fosters the growth of forms of *Commons-based peer production* based on distributed production (Gershenfeld, 2012; Rifkin, 2013). Open and distributed production refers to an emerging collaborative production model which may be web-based or in physical facilities such as makerspaces and Fab Labs. This form of production is going beyond the Maker movement (Anderson, 2013; Dougherty, 2016) and allows an open and close-to-the-user materialization of artifacts.

Distributed Design (DD) is a very recent concept that has a strong link with the two abovementioned domains of knowledge and practice. Essentially, DD connects participatory, open source and DiY design processes with parts of existing production and distribution models, digital manufacturing technologies, thanks to computational capability and systems.

Moreover, Distributed Design - intended as open design for distributed products, services and systems - (Diez, 2018; Armstrong et al., 2019) requires users and indie innovators to

question themselves, to overcome their limitations and to experiment with new ways of making and doing things. Creators and innovators make use of digital-enabling technologies as digital fabrication platforms, prototyping spaces and community-based labs to make tools and tech accessible. Personal and personalized solutions can be created on- demand, on-site, and then shared with others. Recently, the theme of innovation, as far as design disciplines are concerned, is increasingly linked to experimental practices directly related to the dimensions of open and distributed knowledge and production. According to Aleinikoff (2014), *"innovation is a dynamic problem-solving among friends".* Innovation is a practice closely linked to the bottom-up experiential dimension, often coming from a group of users who seek to respond to design niches through the increasing accessibility to spaces, places, communities and technologies more widespread in cities. This aspect can be connected to a constant growth in the dimension of participatory design, intended not only as a methodological approach but also as a spontaneous practice, with the aim of developing design solutions together *with* or *by* the citizens-users.

2. Patient innovation and open care: an emerging scenario

Unquestionably, digital transformation increased innovation capabilities in designers but also in final users. When that kind of design-driven and user-driven innovation become *mission-oriented* (Mazzucato, 2018), it can be work support the autonomy and quality of life of people, especially those affected by diseases or disabilities, as well as their families and caregivers. According to Bertalan Mesko (2016), the development of new forms of care enabled and enhanced both socially and technologically, the increasing digitization of patient data, and the increased permeation of so-called disruptive technologies, acquire a meaning only if they put the person at the center of their action. This means, first of all, strengthening his or her personal knowledge, and making him or her an expert capable of autonomously managing the prevention, self-diagnosis, and collaboration with the doctor to actively participate in the development of his or her own care. It is precisely the emerging trend of active participation by patients - both individually and in the organized manner of associations and caregivers - that brings to light new levers and new ways of innovation. What gradually emerges is the concept of patient innovation (Zejnilović, 2016; Maffei et al., 2017), a bottom-up and user innovation formula that is divided into four main dimensions: design, production-technological, social, regulatory and legislative (Maffei et al., 2019).

As far as the design dimension is concerned, there is an important need to aggregate different skills, professional and non-professional, in a collaborative dynamic through informal design practices. The productive-technological dimension of patient innovation is expressed in the choice and use of technologies - particularly digital technologies - which can also be modified by the patient himself or built ad hoc. The creation of communities united by the desire to solve specific needs, goes to perimeter the social and/or socializing dimension. Finally, patient innovation must necessarily confront (face of) the regulatory and

legislative aspect, which often slows down or blocks the production and diffusion of certain design solutions, as they are not part of the traditional certification chain.

Digital transformation allows patients to access and exchange data and information, create a dialogue with health services and ministries, organise and participate in associations, and raise funds to develop scientific research. The health system is becoming increasingly advanced when it comes to monitoring the body and its physical performance, with biometric data collected by interactive personal and environmental devices.

One of the areas in which this shared synergy can give concrete expression to relevant ground-breaking solutions is the *open care* (Day et al. 2017). Nowadays, types of products such as aids and prostheses can be designed using open source knowledge, software and hardware, and materialized within makerspaces combining makers' skills with digital manufacturing technologies (DeMonaco et al., 2019). Starting from this logic, a multiplicity of different solutions can be conceived and implemented answering to personal or social needs related to diseases or disability conditions. The personal and collaborative dimension in the path of disease management is, probably, the main catalyst that has made possible a series of innovative open care projects.

Within this transformation framework, it is interesting to explore the role of distributed design and production for open healthcare that we go to define as *Distributed Care* (DC), investigating emerging design skills and the use of digital fabrication within makerspaces, distributed labs where bottom-up experimentations developed by communities of makers, professionals and users are recently condensed. In particular, after a preliminary introduction on the main dynamics of open and distributed design, we will try to trace areas of opportunity and criticality, points of convergence and difference that may emerge in designing solutions for DC. The methodology proposed is the analysis of two case studies related to experimental initiatives developed by designers, makers and user innovators, materialized within an Italian Fab Labs, Polifactory - the makerspace of the Politecnico di Milano, and released through a distributed design platform (distributeddesign.eu). The analysis of these experiences in the field will serve to reflect on the development of Distributed Care, an innovation area characterized by a design culture strongly hybridized with the maker culture (Bogers et al., 2010).

3. Distributed design for open healthcare: two stories

Thanks to the systemic interpretation of the main elements of the emerging healthcare scenarios, it has been possible to scale up the proposed interpretation within a funded design project, explicitly conceived to be open and distributed.

FabCare and Next Steps[1] are two experimental initiatives part of Distributed Design Market Platform (DDMP, distributeddesign.eu), a project funded and supported by the Creative Europe Program of the European Commission to implement the global network of Fab Lab promoting and improving the connection between makers and designers with the European market. DDMP is an opportunity to consolidate this network, focusing on the development of a European Distributed Design Market Platform for makers and designers. it is particularly relevant as a specific case study in order to explore the dynamics of product design in the healthcare sector within the Fab Labs.

FabCare (2018) and Next Steps (2019) are experimental initiative promoted and developed by the makerspace Polifactory in order to stimulate designers, makers and independent innovators to design open source products for healthcare that can be distributed through digital platforms and materialized in Fab Labs. Both these experiences aim to demonstrate how designers, makers and independent innovators – also interacting with patients, caregivers and their associations – can concretely design, produce and distribute open source healthcare solutions with a real market potential.

The reasons why this is a relevant case study can be properly traced back to the nature of distributed dissemination with which the project outputs were originally conceived. According to Armstrong et al. (2019), the distributed design idea is one outcome of the intersection of two global trends: the maker movement and the digitisation of the design discipline. The entire DDMP European project integrates design skills and the making approach to enable the development of new entrepreneurial types of professional producers and in the case of the FabCare and Next Steps initiatives, this has generated open and distributed healthcare projects.

The parameters adopted for the case studies analysis are:

- physical and virtual places where the design process become "distributed" (Fab Labs, makerspaces, digital manufacturing platforms, etc.);
- enabling tools and digital technologies used to materialize the solutions;
- kind of solutions developed (e.g. product, product-service, on-demand, customizable, shareable solution);
- actors and stakeholders involved in the design and materialization process (e.g. community of users, caregivers, patient associations, etc.);
- release of the solutions (e.g. marketplaces, open source form although not necessarily free).

[1] Other interesting cases studies that cannot be analyzed in this paper are: *Hackability, Careables.org, Open Rampette*. Detailed information on these cases have been published within the MakeToCare reports (see www.maketocare.it/report)

3.1 FabCare. Open devices for smart monitoring and care awareness

Table 1. Synthetic overview of the FabCare initiative.

Level of analysis	Short description
Places (Physical and or virtual)	Fab Lab, university, medical centre, online platform
Technologies and enabling tools	3D printing, 4D printing, Laser cutting, CNC Milling machine, Electronics, Soldering station,
Kind of solutions developed	Electronic devices and analog products for monitoring and prevention
Actors and stakeholders involved	Designers, makers, researcher, doctors and specialists (CM Santagostino), users, patients
Distribution	Release of the solutions through CC-BY license; download available on the online platform distributeddesign.eu

For the first year of DDMP research, Polifactory based on the experience gained in the healthcare field, thanks to the MaketoCare research initiative (makertocare.it). Nowadays, types of products such as aids and prostheses can be designed using open source knowledge, software and hardware, and then be materialized in Fab Labs combining makers' skills with digital manufacturing technologies. Starting from this logic, a multiplicity of different solutions can be conceived, intertwined and implemented answering to the needs of prevention or care for everyone. The experimental initiative that has been developed has taken the name FabCare, with the purpose of stimulating designers, makers and independent innovators to design open source products for healthcare that can be distributed through digital platforms and materialized in Fab Labs. FabCare was developed by Polifactory, within the Distributed Design Market Platform project. Therefore, FabCare's challenge aims to demonstrate how designers, makers and independent innovators – also interacting with patients, caregivers and their associations – can concretely design, produce and distribute open source healthcare solutions with a real market potential. Furthermore, Fabcare was technically and scientifically supported, as well as endorsed, by Centro Medico Santagostino, that is one of the first Italian network of specialist polyclinics managed by a social venture capital company, and it is aimed at experimenting healthcare service models economically sustainable and socially responsible.

The whole project lasted only a few months: from May to October 2018, FabCare has developed an intense mix of events and activities. The main milestones of the project were: (i.) the Open Call for Ideas, (ii.) the selection of ideas to prototype, (iii.) the projects' implementation and materialization, (iv.) the projects distribution and promotion.

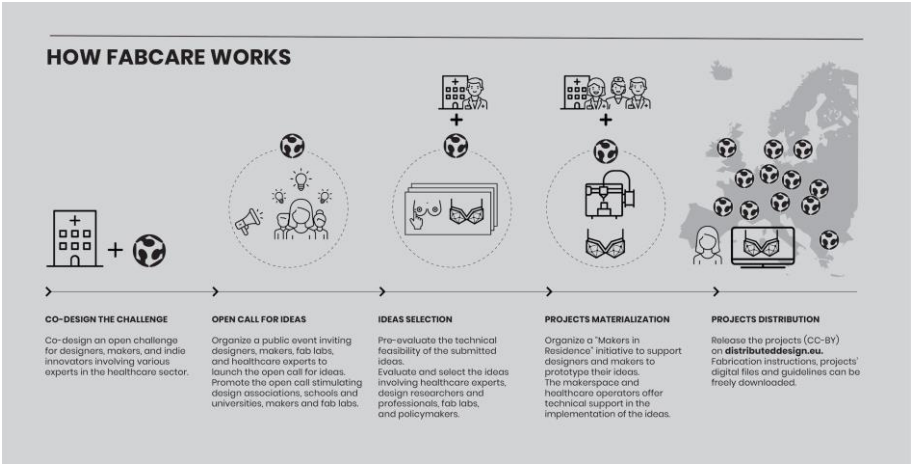

Figure 1. Fabcare's project phase scheme

First the Open Call for Ideas (i.) was co-designed, launched and promoted. Polifactory and CM Santangostino have collaborated to define themes and design challenges, and participation rules for designers, makers and independent innovators. Then, FabCare's Open Call for Ideas was officially released during the European Maker Week, and from May to July the it has been promoted to the italian Fab Labs network and the main design schools and university in Italy. Afterwards the selection of ideas to prototype (ii.) was made. Starting from a list of twentyone projects submitted by a group of sixty designers and makers, in July 2018 a panel of experts in design, healthcare and digital fabrication have selected the five ideas to be developed and prototyped within Polifactory. The winning ideas were: DermAware, Dermap, Mole Mapper, Palpatine and Zero2. It is important to note that they are specifically defined as ideas, because they were mainly interesting intuitions and concepts, still far from the logic of open and distributed design and production.

For this reason, the evolutions acquired during the phase of projects' implementation and materialization (iii.). From July to October 2018, seventeen designers and makers have operated in Polifactory with the aim of developing the five selected projects. During the phases of executive design, experimental prototyping and digital fabrication they have been supported by a network of technicians, professors and researchers of the Politecnico di Milano. In the end the phase of distribution and promotion (iv.) was held. The five projects were published on the platform distributeddesign.eu and on Polifactory's website, thus promoted and presented at European Maker Faire Rome through an exhibition and a talk.

Despite the fact that these are projects with very different complexities, it is important to emphasize that anyone can actually reproduce them, because for each project the documentation is still available online, which includes digital files for production, fab-instructions, and the user manual. It is important to point out that all projects developed

within FabCare are not medical devices. These are open source solutions at the first stage of release and development that can be freely implemented following the instructions provided by the CC-BY license. All FabCare solutions provide informative support and/or help with prevention or monitoring activities regarding the problem or pathology for which they were designed. In no case can these solutions replace a consultation or relationship with a doctor or a medical specialist.

Figure 2. From left to right and from top to bottom: "Dermap", a device that supports people in measuring the evolution of their vitiligo, designed by Marianna Accorsi, Giulia Sala, Giuseppe Valentino; "DermAware", a digital bracelet to educate people on the burden

associated with atopic dermatitis, designed by Nicolò Bisi, Nur Eral and Mattia Fantoni with the support of Angelo Geraci, Nicola Corna, Fabio Garzetti and Nicola Lusardi; "Mole Mapper", a small tool for your skin health. Keep your moles in check and share info with your doctor, designed by Ilaria Vitali, Patrizia Bolzan, Mila Stepanovic; "Zero2" a device for patients with respiratory deficiency used to monitor their blood oxygen levels, designed by Tommaso Brioschi, Lorenzo Lanzoni, Giovanni Luca Fidone; "Palpatine", an analogue wearable educational device to learn the correct breast palpation techniques, designed by Francesca Poli, Daniel Sanchez, Benedetta Beltrami, Luca Sommariva, Chiara Parise.

3.2 Next Steps. Co-designing open source walking aids

Table 2. Synthetic overview of the Next Steps initiative.

Level of analysis	Short description
Places (Physical and or virtual)	Fab Lab, university, co-design workshop, online platform
Technologies and enabling tools	Available walking aids, 3D printing, Laser cutting, Electronics, Soldering station,
Kind of solutions developed	Aesthetic and/or functional solutions for the customization and reconfiguration of walking aids
Actors and stakeholders involved	Designers, makers, researcher, patient association (AIG), healthcare company (Sanofi Genzyme), lead users, patients
Distribution	Release of the solutions through CC-BY license; download available on the online platform distributeddesign.eu

In the second year of the DDMP project, Polifactory has once again proposed to work on the issue of healthcare, this time articulating differently the identification phase of the project areas of intervention. The new action, called Next Steps, started from the desire to stimulate designers, makers and patients (as user innovators) to co-design and prototype a collection of open source walking aids that can be distributed through digital platforms and materialized in Fab Labs. Next Steps was developed thanks to the collaboration with Italian Glycogenosis Association (AIG), a patient association that represents people affected by this rare and degenerative metabolic disease. AIG prompted the involvement of patients in the co-design and prototyping of walking aids and for that very reason, the whole project was built around the co-design phase. Thanks to Next Steps, patients were able to experience a real process of patient innovation. Next Steps was articulated in three steps: (i.) the Challenge assessment; (ii.) the Maker in Residence activity; (iii.) the the projects distribution and promotion. During the Challenge phase (i.), from March to May 2019, the starting point was an open call to action that stimulates the engagement of a group of patients that will be involved in the co-design of walking aids together with a team of designers and makers of Politecnico di Milano. During the Challenge phase, the product ideas were presented and

shared with AIG, within one of more events. Patient innovators such as Antonella Ferrari[2] caregiver innovators such as Fabio Gorrasi[3] were able to participate in this phase.

From May to September 2019 the Makers in Residence phase (ii.) was held. In this phase patients interacted with the designers who supported them in the development and prototyping of open source walking aids, thanks to the technical and scientific support provided by Polifactory, and the medical and scientific support provided by Sanofi Genzyme.

The last step, the promotion and distribution of the projects (iii.), took place in September and October 2019. As for the previous edition of DDMP, the results of co-design and prototyping were published both on the distribuddesign.eu platform and on the Polifactory's website, and were also presented in Rome during a speech at the European Maker Faire 2019, and in Milan during the Manifatture Aperte event. Reflecting on the previously established co-design phase, an in-depth examination of the type of information obtained by strengthening the involvement of patients and caregivers is reported.

The results of a first survey with the patients from AIG association, the suggestions received by the patient-innovators during the co-design workshop, and the feedback obtained interacting with patients and their families during the AIG meeting evidences aspects that influence the design phase. First of all, the aesthetic dimension of the walking aids is as important as working on functional aspects. Secondly, walking aids tents to become physical extensions of the people; personalization is an important issue because characterizes the identity of the walking aids in order to be tuned with that of their users. Then, Next Steps solutions must be adaptable to the walking aids already available on the market. Last but not least, the digital manufacturing processes and the digital technologies embedded in the walking aids have to be adaptable for DIY, makers and Fab Labs, craftsmanship but also industrial sector. The result was four projects, focusing on different aspects of walking aids. The first project is Twistr, a parametric stick that has developed a design and digital fabrication method to materialize personal parametric sticks – with kinect and grasshopper – having a 3D printed structure. The stick is printed with the carbonium material. Another stick project, this time made with a generative logic is called Taylor. This is a project of a method to create generative sticks, which change according to the weight, height and gender of the user. Another result was the project of an IoT rollator named Wander3d.Thanks to this hacking it is possible to transform a traditional walker into a motorized and sensorized object. The user can activate or not the motors according to the needs. The last project dealt with the aesthetic dimension of walking aids. Clip Clap is a project that allows the personalization of your crutch. This project concerns the co-design of removable clips for all

[2] Antonella Ferrari is an Italian actress suffering from multiple sclerosis who, acting as an innovative patient, has designed and developed her own collection of hand-decorated crutches.

[3] Fabio Gorrasi is an Italian caregiver innovator who has designed and make a special brace for his daughter affected by Spinal Muscular Atrophy, in order to give her more movement and freedom.

kinds of crutches that can be easily personalized and digitally fabricated. The projects developed will have to be available in open source mode according to the Creative Common License (cc-by and cc-by-sa).

Figure 3. From left to right and from top to bottom: "Twistr", the parametric stick designed by Angelo De Iesi, Andrea Ascani, Ewoud Westerduin, Aurélie Marie Glaser; "Taylor", the generative stick designed by Alessandro Ceriani and Marco Ceruti; "Wander3D", the IoT rollator designed by Leonardo Lucchetti and Silvia Meregalli; "Clip Clap", the customization of crutches designed by Lorenzo Cereda, Nicola Colombo, Giovanni Cortellessa and Andrea Stefanelli.

4. Designing for Distributed Care. A new scalable model?

The literature review and the experiences analyzed stimulate two levels of reflection.
The first level concerns the key elements of a distributed design and production process for the development of open source solutions in healthcare. The second level concerns the characteristics and properties that define Distributed Care as a possible area of innovation.

The analysis of project experiences in the field identify the following key elements previously highlighted in the summary tables of the initiatives:

- *Actors.* The importance of cooperation between heterogeneous subjects such as designers, makers, but also specialists in the institutional care sector, patients, caregivers and associations. Distributed design stimulates the creation of transversal project teams that participate with different contributions in the development of the final solutions, especially during the initial phase that range from needs analysis and development of the project brief.
- *Places*. The importance of the places where the project development process is materialized. From the initial idea to the final solution distributed design generates a progressive delocalization of the innovation process. In fact, the first phases generally need the support of different "physical" places that function as "facilitators" and aggregators of (Fab Labs, research labs, medical and rehabilitation centers, schools, etc.) where the different subjects involved in the project development have the opportunity to meet, confront each other, work together. The prototyping and design development phases generally take place thanks to the support of a Fab Lab network.
- *Technologies.* The importance of the access and use network of advanced digital manufacturing technologies thanks to which production can be customized, decentralized and potentially close-to-the-user.
- *Distribution/release.* The importance of the concept of "openness" applied to the distribution and release phase of the final solutions. Distributed design makes the solutions accessible and materialize everywhere by downloading digital files from peer-to-peer platforms (e.g. GitHub). The available documentation allows to elaborate subsequent customizations and implementations of the solution, opening the entire design process and connecting it to a distributed production network.

What can we learn from the promising direction of distributed care?

- *Not only medical devices:* Distributed design promotes and stimulates a biodiversity of solutions, exploring the theme of prosthetics, orthosis, medical devices and a new generation of personal objects. Many solutions – especially in the field of healthcare – are influenced by the regulatory system, which is fundamental to protect users and patients. This is a bottleneck for distributed design, but it is also an opportunity. The development of non-medical devices can be complementary to medical ones. Distributed design can support users and innovators to create solutions that demonstrate how existing rules, standards and market barriers could be reconsidered.
- *Not only functional solutions*: Many solutions are designed following functional and technical requirements, but their aesthetic dimensions can be as important. Healthcare objects and aids tend to become physical extensions of people. Aesthetic personalization is important, because it characterizes the identity of objects and establishes a personal or familiarity for users.
- *Not only complex and expensive solutions:* Many objects and devices are complex and expensive. Distributed design can design solutions that can be adapted from

objects already available on the market, taking into consideration open hardware and low-cost technologies that are easily accessible for the everyday user and disadvantaged or vulnerable people.

- Not only new products: Many objects are unique and irreplaceable owing to a relationship that is established with their users and owners. Distributed design perfectly fits with hacking, repairing and upgrading practices and is compatible with remanufacturing and refurbishing processes.

What's next? We could be at the beginning of an augmented concept of 'care' where people can develop a distributed awareness, responsibility and participation in the design of innovative open source solutions that work to take care not only of people, but also other living beings and the environment. This can be Distributed Care.

Heterotopia of Space: How capitalism is alienating and controlling societies

Sarah Khayat

Lebanese International University
*Sarah.khayat@liu.edu.lb

Abstract | Multimedia has historically been the tool of choice preferred by political capitalism to gain control over people. This has been massively aided by the upsurge in the political sector's machinery and progressive technology. Governments, and the private sector control multimedia tools such as advertising, social media platforms and technology to control people. Cities have risen to become heterotopias; vast-growing high-tech infrastructure capitals that transform people's behaviour. A marked change was visible in the 21st Century. Technological devices previously only available to governments and the military became commercialised, packaged and marketed to people. In our capitalist consumer societies, such private sector corporations take advantage of social media platforms to further control social groups largely influencing their politics. The private sector, through its multiple alliance to governments, moved to exploiting technological tools commercially. Thus, progress became a basic process solely for gaining power and control over people.

KEYWORDS | CAPITALISM, CONSUMERISM, IMAGERY, SPECTACLE

1. Introduction

This paper defines heterotopias as manufactured spaces that alter people's behaviour. In this day and age, it is very easy for governments, together with the private sector to manipulate multimedia platforms to create spaces where human behaviour can be controlled, almost expected. This paper sheds light on these manipulative practices by governments taking examples some historical, some modern, to exemplify how people's behaviour can be almost orchestrated. A consumer society relies heavily on progressing its technology. Accordingly, technology took the upper hand guiding mankind's gaze. As Virilio noted, "one can only see instantaneous sections seized by the Cyclops eye of the lens" (Virilio,1994, p.13). However, for Debord sight is "the most abstract of the senses, and the most easily deceived" (Debord, 1995, p.17). Thus, in a world that is mirrored by images, reality is lost to the point of being obscured and even non-existent.

Multimedia has historically been used exploitatively with large socio-political implications. Originally, advertisement has been manufactured to lull public opinion. This has been achieved through the use of attractive visuals. Images, then, have become the new norm used by governments, and the private sector to derive their legitimacy in societies armed with technology. Previously, the exploitation of people, particularly the proletariat, was made by normalizing societal conventions through a visual illusion of imagery. However, today, this can be achieved through different online platforms as images spread instantaneously. This maintains cultural and political sustainability and ensures governments and corporations stay in place through the ongoing argument that people need government protection as there is always a security threat and people will always need things to consume. Our behaviour is currently controlled by the images that we see online. Online platforms provide us with an arena for interconnection as well as for discovering difference. While there is a high degree of homogenization, it is imperative to note that there is also forms of diversification.

Visual communication literature addressed topics relevant to the exploitive image and how it's used for changing social perceptions. Government's newest trend is creating a hybrid image that juxtaposes violence with refined spectacle. It becomes impossible for some spectators to identify this metamorphosis. This is an approach that rounds people collectively leading to a homogeneous society. This method is used by governments and the private sector to control people by manipulating codes and symbols. Ideologies of suppression and obeisance are hidden in imagery that are innocently absorbed. Although ideologies have been reconstructed over time reflecting democracy, across societies yet, democracy has been long dead. It is only the illusion of democracy that we find across countries and societies nowadays. Dictatorship is ever present but is concealed behind concepts and imagery. In *One-Dimensional Man*, Marcuse suggested that with "technical progress as its instrument, freedom-in the sense of man's subjection in his productive apparatus-is perpetuated and intensified in the form of many liberties and comforts" (Marcuse, 2002, p.35). Voting, freedom of speech, debates, open arguments, advertisement

all reflect an image of a liberal, democratic, equal, representation society. By taking part of governmental decisions, the majority of individuals think they are free under totalitarian regimes.

As societies advance technologically so do corporations driven by capitalism. Private sector corporations used technological developments, to camouflage its exploitive tendencies. Governments and the private sector have become intertwined and synonymous due to their enmeshed interests. They hide behind a polished and mediated representation. Societies become more and more intertwined with the spectacle, but also alienated due to their experience with mediated representations. For Debord, "the spectacle is not a collection of images," but a social relation among people mediated by images" (Debord, 1995, p.12). He considered that anything representative can alter reality and may be harmful.

Today, with these easily affordable devices, imagery and the spectacle that has been commercialised by the private sector people can be reached collectively, thus rendering images more dangerous and exploitive. The purpose and use of images with new technologies has highly affected image production. These technologies were able to copy the image of the actual in the virtual. It bred a duplicate, almost virtual, space within the actual where societies can move from one interactive space to another. "This act of cutting reality into a sign and nothingness simultaneously doubles the viewing subject, who now exists in two spaces: the familiar physical space of her body and the virtual space of an image within the screen" (Manovich, 2002, p.104).

Not only did these new devices change the way people communicate and interact but it changed their behaviour and perception as they continuously disappeared inside the virtual. Technology took control over the body as people are delving more inside the virtual. Virilio's point of view on these new technological devices is that it will "colonize human behaviour, just as television and the computer are doing, but this last form of colonization is a much more intimate, and a much irresistible form" (Virilio, 2000, p.51). Since many people are equipped with these tools, such societies become intertwined inside webs of technologies that are communicative, interactive, mobile and more importantly monitored and observed.

2. Aestheticization and the image

Totalitarian Governments have historically exploited artists to camouflage and propagate messages aesthetically. Before the industrialization of the screen, images were passed on differently. For example, in his essay, *The Work of Art in the Age of Mechanical Reproduction*, Walter Benjamin argues how political regimes can exploit new machinery. Previously, with inventions like cameras, film and printers which can distribute messages equally leading to a collective response.

Historically skilled painters, sculptors, or craftsmen were commissioned by patrons. As churches grew in power, so did the development of its artistic flair. Artists created artwork

as truthfully as possible filling it with illusion through a dynamic display. That said, it was designed to impress. In order to hone its message churches commissioned artists to spread its holy image to the public. City streets, towns and public shrines were covered with art, associated with the church's influential power. This type of art was made to appeal visually and emotionally to the public. Comparing this to the Nazi regime who exploited the use of new emerging art media like films, newspapers, the radio, advertisement, symbols, speakers, ceremonial events, exhibits and schools, which all exemplified as Nazi propaganda and exploited the public opinion. This is when Benjamin differentiated between two poles, exhibition and cult values. "Originally the contextual integration of art in tradition found its expression in the cult. We know that the earliest art works originated in the service of a ritual – first the magical, then the religious kind" (Durham G.M. & Kellner M. D. 2006, p.22). He asserts that exhibition value had exceeded its dominance over cult value as the first can be distributed faster. These inventions changed the functionality of art that was only used for cult and religious ceremonies. Within the framework of Marxism, Adorno and Horkheimer's essay *The Cultural Industry: Enlightenment as Mass Deception,* inspects the use of such media are propagated within the arts particularly during wars to gain control over the people. "Culture today is infecting everything with sameness. Film, radio, and magazines form a system" (Durham G.M. & Kellner M. D.,2006, p.41). This allowed political regimes and governments to control and divert human behaviour and perception according to the imposed system. "The basis on which technology is gaining power over society is the power of those whose economic position in society is strongest". (Durham G.M. & Kellner M. D.,2006, p.42). Within these media of films, radio and magazines, propaganda becomes harder to distinguish, for some, when it's aestheticized and blended with art.

Another more recent example of governments manipulating public opinion through imagery is the United States diverting public opinion by selling an image of a picture perfect life. *Picture-perfect America* is known for its nation building, technological military advancement, and financial means. Although the United States is also known for exploitation of slavery, imperialism and racism yet any anti -humanitarian atrocities committed by this nation has been camouflaged with a polished spectacle. Identified as "a visually striking performance or display" (Spectacle, para 1), the spectacle of the United States was fed to its people by advertisement and films. With the advancement of visual communication devices, the US as Debord noted "It has invented a visual form of itself "(Debord,1995, p.14). As a predominantly capitalist consumer society, some of its citizens are living the glamour of the United States. Therefore, this psychedelic image was manufactured by media. Its beliefs and values have been constructed through its Hollywood image where other societies struggled maintaining their culture because they tried replicating a phantasmagoric image.

In a controversial title, *The Gulf War Did Not Take Place*, Jean Baudrillard argues that this war was a virtual war produced by the media. The only access to the public to see the events of this war was through the US media like CNN. "It is a masquerade of information. No images of the field battle, but images of masks, of blind or defeated faces, images of falsification. It is not war taking place over there but the disfiguration of the world"

(Baudrillard, 1995, p.40). The real events of this warfare disappeared behind the curtain of simulated reality made by the media and images. “The build-up is unreal as though the fiction of an earthquake were created by manipulating the measuring instruments” (Baudrillard, 1995, p.26).

This was a modern speculative war promoted by the media in a form of global entertainment and suspense. It was a broadcasted war that took place on the screen. In an interview with Paul Virilio, he stated that the Gulf war was considered a live war. (Virilio, 2004, p.66). This war was taking place globally and on every screen. But because the United States controlled the media, the image of this war propagated globally, from the US point of view. Very little was revealed from the actual combat between the American and Iraqi armies. What was exposed about the reality of the combat to the public was one sided. The United States wanted to promote to its public a strong and heroic image in order to maintain a hierarchal dominance. Their audience was introduced to a new militarized media that depicts a spectacle image and patriotic illusion.

For Baudrillard’s explicit view about the United States is that “it is neither dream or reality. It’s a hyperreality “(Baudrillard,2010, p.28). “The whole country is cinematic” (Baudrillard, 2010, p.31). Through different media devices, the world of advertisement expanded. The placement of ads varied from billboards, to buildings with screens, or popping out randomly on different social media platforms. This excessive bombardment of advertisement is infused with multiple forms of ideologies. Directed by John Carpenter, *They Live* is a Hollywood film that illustrates a typical consumer society that is ruled by a Capitalist government and its private sector. The film exposes how advertisement can spread ideologies and things to consume that lay within its spectacle. The glasses in the film exemplifies living a hyperreality of the fake and real. For Zizek wearing the glasses is “you see the dictatorship within democracy” (Zizek,2012, 02:58). When Nada wore the glasses, he saw what lies beyond the ads. What seems to be innocent, is a spectacle of control, and regulation. Through the ads, there is a message that promotes reproduction, sleep, and consumption. Zizek explicitly illustrates the strange lengthy fight between the two characters which represents the fear of stepping out of societies’ norm. This shows how people crave the hypnosis of ideologies since it embodies a comfort zone. Frank’s character illustrates the majority of daydreaming individuals who refuse to wake up to the ugliness of its society and the evil of these corporations. Zizek identifies this rejection, associating it to fear and pain. “To step outside of it, it hurts, it is a painful experience” (Zizek,2012, 04:42).

3. The King and Queen’s Gaze

Methods of people control exerted by governments throughout history has always changed in ‘how’ it dominates people. Early on, societies normalize traditions in order to control the public’s views, tunnel sight, and behaviour. Overtime, methods of control obscured what was once visible into becoming invisible. Michel Foucault identified representation as a

process of symbolization or coding linking it to power. To this, he examines Diego Velázquez painting titled *Las Meninas* dated 1656 and how power and hierarchy is presented in this painting yet remains invisible to the spectator's eyes. Velázquez painting captures a photographic picture of the Spanish court. The skilled artist steered the viewer to look at particular figures and angles in the painting. What is visible in the painting is what the artist gave emphasis on using light and dark contrast. Relatively, Velázquez directs the viewer's gaze on specific subjects and hides those who are in power. Both figures of the king and queen are obscured in a mirror placed in the middle of the artwork who gaze back at the oblivious spectator.

In the Middle Ages, the image of power was made visible to the public gaze. The image of power was visible to the public through public executions. Those were purposely visible for implanting an image of power and control over people. Pain and torture were used as punishment applied on the physical body. This reminded people of the authoritative power commanded by rulers. Torture devices varied in their instruments and practice. They were exploited in accordance to the severity of the crime. "Skilled torturers would use methods that delayed death while inflicting agonizing pain" (Foucault,1995, p.34). Therefore, the image of pain was key instrument used to exert control.

Public executions were somehow ceremonial and entertaining. "The tortured body is first inscribed in the legal ceremonial that must produce, open for all to see, the truth of the crime" (Foucault, 1995, p.35). It publicized a specific image of justice – that of cruelty. So, in order to restore peace, abolishing riotous behaviour is a must in societies. The convicted used to endure public humiliation and physical pain in the most indisputable abhorrent ways. Because this power exposed its barbaric methods in public spaces, to some extent it normalized its barbaric ways onto its subjects. This form of power controls the public through the implementation of violence on bodies.

In modern societies, public torture is no longer used as a means of public control. New forms of power have emerged and replaced older ones. Works of architecture such as prisons replaced public executions. Instruments of torture gradually disappeared from public spaces and punishment was concealed behind prison's walls. Additionally, other forms of discipline were conducted by different institutions. These new forms of power are different from medieval ones. The new power wanted to create obedient bodies that self-regulate according to the laws. "For example, institutions as schools, hospitals, and military are places that train individuals to self-regulate" (Foucault, 1995, p.136). These institutions became the norm of societies and concealed the system of control behind its disciplinary and cultured methods making it almost invisible to the eyes of the public. With technologies, power becomes invisible. Similar to Velázquez painting, it also gazes at the spectator directly and from every angle. "This power had to be a faceless gaze that transformed the whole social body into a field of perception" (Foucault,1995, p.214). These devices allowed visibility to be everywhere. Watching people from multiple angles can be seen in Jeremey Bentham's architectural design, the panopticon. The panopticon is a central tower from which prisoners

could be observed. Because the tower is always lit; prisoners assumed that they are being watched at all times. Consequently, these devices function as Bentham's panoptic tower and Velázquez mirror. The spread of these devices within societies in order to monitor people, from any point in space and time thus making everything visible. Today, many public spaces are equipped with machinery that monitor everything. However, the system of control and power is hidden and remains invisible from the eyes of the public. With the new technologies, the mirror from Velázquez painting is positioned in the heart of societies as Bentham's panopticon. In consequence, totalitarian regimes become invisible to the naked eye and it's "gaze is alert everywhere" (Foucault,1995, p.195).

This illustrates how the structure of the panopticon and Velázquez mirror is reflected in tools such as the CCTV, global positioning systems, wireless internet, smart mobile phones, smart watches and many more which are employed everywhere in the physical space. This in turn creates an augmented space, identified by Lev Manovich as "a space of monitoring and control" (Manovich, 2002, p.5). Therefore, an augmented space is a space of surveillance because these technologies function as the panoptic tower and Velázquez mirror. Therefore, the invisible gaze of the king and queen had moved from center of the court to be everywhere because of these devices. The power of the capital is reflected behind the shiny screens of these devices, creating different levels of control. Today, both the actual and virtual are spaces of monitoring and control over the masses.

4. The Shift of Heterotopias

Currently we live in heterotopias, spaces created by the government and private sector that control the way we behave. A utopic society represents a perfect image of itself. It is identified in Oxford Dictionary as, "an imagined place or a state of things where everything is perfect (Utopia, para 1). On the other hand, heterotopias are other places, spaces that relatively carry several layered meanings and are characterized by juxtaposing different settings together. "We live inside a set of relations that delineates sites which are irreducible to one another and absolutely not superimposable on another" (Foucault, 2006, p.23). Heterotopias subjugate people in several spaces. Because heterotopias are part of a social structure, people are unaware of their existence as they are naturalized within the social system. They become natural and part of societies norm. Heterotopias have many characteristics and are experienced within the frames of culture. The masses are unaware of the existence of such spaces that are used for reconstructing behaviour. These spaces are used as a form of control over the body. People in heterotopias behave according to the place they are in.

Some heterotopic examples can be relevant to urban spaces, as they are able to juxtapose different places and environments together. Moreover, they accumulate time, preserving the past such as Foucault's example of museums, libraries or cemeteries where the body is persevered. Another characteristic is that they can create a non-existent imaginary place as

well as differentiate and categorize people within groups and identities. Since people are living in online landscapes, heterotopias then are experienced in the virtual realm. As Foucault had noted, the existence of heterotopias is to regulate, examine, and restructure societies and people, for example the prison is a heterotopia. Although they seem harmless, yet they can regulate and discipline society's behaviour. Since mankind is currently swinging in spaces of virtual and actual, mankind is nevertheless living the heterotopic "placeless place" (Foucault,2002,p.4). Online landscapes reflect a "placeless place or a place without a place" in virtual reality. Going through the World Wide Web, social media, google earth and other spaces are all kinds of heterotopias.

The virtual has the ability to create heterotopias that originated from spaces of society. Since many societies are wired with virtual spaces, therefore they adapted their behaviour to virtual agreements. Today, the actual space relies heavily on the virtual as most of its daily operations are conducted online. Businesses, finances, finding locations, interactions, and money transactions are conducted virtually. Online landscapes are colonizing societies inside its cybernetic frames that are limitless with its boundless pot of networks that promises the manifestation of any human desire. The new maps of many civilizations become identical because of World Wide Web and social media.

Societies find themselves more immersed in these happier spaces. These spaces are considered the new heterotopias as they impact people's behaviour and actions. What people experience within online heterotopias are different than the ones in the actual. They can regulate and control people's behaviour targeting specific areas such as consumption of commodities. For example, virtually, people are engaged in images. The image of fame, identity, lifestyle, and youth stream everywhere within these spaces. Virtual heterotopias are prevailing over reality and over the actual space leading societies to fall inside its illusions and imagery. And while consumer societies aim for similarity through fashion and style, this is leading to mass-producing behaviour. This alternative reality may lead to dangerous delusions. Adapting in the virtual heterotopia meaning sustaining self-image but leading to loss of identity.

The image of delusion and loss of identity heads in the direction of plastic surgery. The art of modelling flesh becomes the trend of consumer societies. The obsessiveness of extending youth resorts to extreme reconstruction of the body in order to maintain the youthful look in the virtual. Not only fashion can print a specific look with clothes and accessories also plastic surgery can print bodies. Duplicates of bodies, and faces exist because of these surgeries. Societies are living in the delusion of these images inside the virtual. They are trying to mimic and look as their virtual image. The strains of the virtual is maintaining the fake identity that lives differently in the physical. This is how new heterotopias operate on regulating societies as the focus today is mostly on appearances. Instead of controlling behaviour with instruments of torture, people are going under the knife willingly through surgeries in order to enhance their self-image. Furthermore, controlling people's behaviour goes further towards what they consume. Since heterotopias are known for merging sets of places

together, social media is a place where the intertwining of places is formed. Social media tools like Instagram and Facebook merge things together. The user can go live, play games, shop, promote, follow pages, create pages, watch the latest news, among other activities. These spaces offer new ways of living as users become more dependable on them. Whether food, clothes, shoes even sports, people behave in a specific way according to the language of the virtual. Opening businesses is possible and easy virtually. Everyone can go online and promote their commodities and goods. Instead of investing growth in real urban spaces, businesses now aim to grow virtually. More Instagram followers means product popularity. Investing in followers and fake social media accounts, is used to gain consumer trust and increasing product sales. These virtual businesses are their own advertisement agency in marketing and promoting themselves.

With easy and inexpensive strategies like following accounts casually, random discounts and shout outs, online challenges, collecting funds for a cause, and free give away. Seeking popular online bloggers with over a million followers to promote merchandise is essential. Virtual businesses implement regular strategies and the linguistic language of the virtual space, were consumers are swayed by these strategies falling into this trap of virtual spectacle. The new heterotopias of the virtual space controls societies to behave and consume in a specific way. In the current consumer societies, people are completely alienated from their actual space and have no sense of identity as they behave, dress, and look the same.

5. Conclusion

Images created by processes within a capitalist system: one that is controlled by both governments and the private sector due to their common interests, have created communication tools such as film, advertising, and online platforms reaching global destinations, crowding out place-specific identities. This capitalist modern system has succeeded in alienating societies stripping it from its identity, physical body, and urban spaces. “It’s the disappearance of the place and the individual at the same time. It’s now proven that this technique is spreading all over the world. It’s easier to make people disappear one by one, ten by ten, or thousands by thousands” (Virilio,2008, p.147). Although it might seem that these technologies had helped societies however, stipulated a specific way of living in a capitalist consumer society.

While we think we are living in enormously technologically sophisticated worlds governed by democracies and catered for by the private sector, this is nothing more than an illusion. As our lives became more virtual, politics and Capitalism resulted in exploiting the internet and social media for their own personal benefit. Methods of control vary from trending a cultural demand to distract people with the latest fashion and trends, to services and products, to abusing global information systems and bombarding populations with endless and useless information to the point of conditioning human response to it. As capitalist consumer

societies continue to grow, their individuals latch onto these technologies as if they are means of survival. Yet, these societies are failing to see the exploitive tendencies of these devices since their communication was made easier. Consumer societies directed by capitalism are alienated from the fact that to some extent behave, act, in the same manner. Moreover, they are monitored and observed from every single point by the panoptic gaze.

Abstract | This subject-object oriented research, in post-industrial socio-economic condition, refers to a protocol design on reading industrial objects and measuring how their "hyper value" increases. The term idiosyncratic design will be read as a logical protocol, to be transferred in its digital performance. At the same time, software and its projection on computational design will be read as a tank of instructions– created by subjects – that awaits a subject to schematize them and, eventually, construct his own map of expression. Therefore, idiosyncrasy as the evolution of the designer's description language becomes an expressive medium to produce new predicaments (in the Aristotelian logic). The purpose of this paper is to present a relational epistemological map of “idiosyncratic software”.

KEYWORDS | IDIOSYNCRATIC DESIGN, EPISTEMOLOGICAL MAP, LOGICAL PROTOCOL, SUBJECT-CENTRIC CULTURAL IMPRINT, POST-DESIGN

1. An ontological approach on the idiosyncratic object

1.1. Idiosyncrasy as a medium

According to Hippocrates, who first formulated the theory of the four peculiarities in his work "On the Nature of Man", idiosyncrasy is the particular/unique way a person reacts and expresses his feelings or his particular organic or psychological state and mood by which reacts to external stimuli. The etymological analysis of the word relates to "unique" - "plus" - "crassos", which in ancient Greek are interpreted as "unique blend". However, the English translation as "temperament" is also interesting; here, temperament, taken as a behaviour pattern, relates to a time condition from “Tempus”(Merriam-Webster, n.d.).

It is difficult to fully grasp the definition of idiosyncrasy. However, we can denote that it has a dynamic base through which it can be perceived as an open, “metabolic” process that expands in time. It is open because it cannot be set into a stable and concrete meaning, due to the multitude of the different perception frames each subject creates for every stimulation. These frames create properties-substances which enable metabolic reactions from the subject as they relate the logical and the emotional parts of humans’ behaviours. Additionally, timeliness can be perceived both as the human temporal perception in a given moment of time and in terms of a broader cultural evolution of the notion per se.

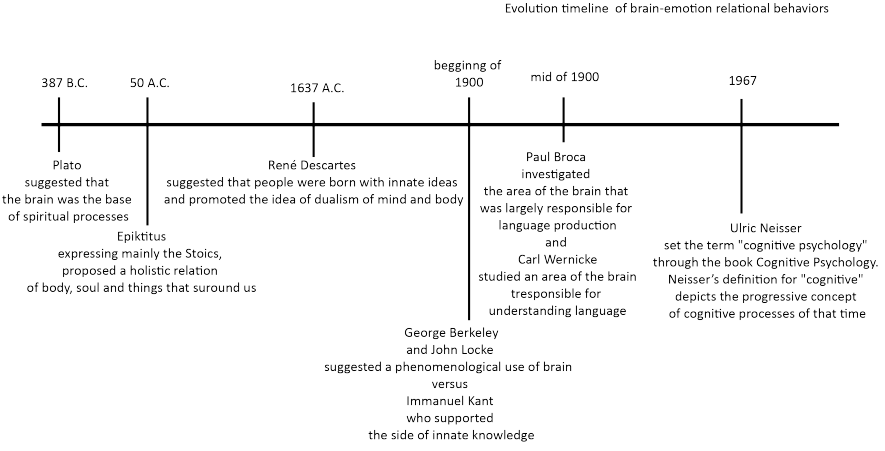

Figure 1. The conceptual evolution of brain-emotion relational behaviors.

According to the chronological line above, the emergence of humans' cognitive processing is directed through the divergence and convergence of the soul-brain function. The term "knowledge" refers to all these processes through which sensory input is transformed, reduced, stored, retrieved, and used. Knowledge deals with all these even when operating without proper stimulation, like with images and hallucinations. It is a dynamic phenomenon

that is inherent in every individual personality but evolves alongside it. Also, however, there is an intermediate/hybrid behavioural condition, referring to the blending of brain and soul. This hybrid condition is the personal filter or medium, both as an in-between as well as an operational condition.

By examining the relation of reason-emotion we can recall references on a mechanism on the definition of the relation between Subject and Object. In that context, we cannot omit to mention Merleau-Ponty, Foucault and The Dispositive, Agamben and The Apparatus, the Gestalt theory, and Zizek with the Parallax view. Although their extensive analysis will not be examined in the present work, we could summarize them under the formula: “what I see relates”. Therefore, when the question "what is this" pops up, instantly a chain of relations emerges, which are defined by the properties the Subject embeds to the Object of question. The properties are placed into the context in which "this" is, transforming the Object into “it is”. Nevertheless, it is important to clarify that the concept of “this” is not related to a psychoanalytic framework of perception, analysis, and interpretation, but is closer to the concept of the “thing”.

Hence, the mechanism of idiosyncrasy is a method of perceiving and conceptualizing the Object ("it"), and we can say that it is linked to the notions of exhibiting and curating. As such, it extends to the construction of a collective thing as a real-time interpretation. Examples of such mechanisms are both Aby Warburg's Mnemosyne Atlas (1930) and Herbert Bayer's curatorial mechanism in the historical "Points of View" exhibition in 1930 (figure 2, 3). In the first example, Warburg's very personal aesthetics and philosophy can be interpreted as a whole that produces generalizations. These extensively mapped generalizations serve as his own insight of a (new) knowledge and have the potential of becoming collective. The second one proposed a visual mechanism through which the observers created their own perspective through multiple views about the exhibited items. What is common in both examples is the ability to relate hands-on cultural perception and memory. Although the senses, as receivers of idiosyncrasy, are the way that materiality provides reminiscence and forgetfulness, as Hamilakis points out in his work "Archeology and the Senses: Experience, Memory and Emotion", p. 25, the fact that the Subject becomes a part of a testimony process reveals an enhanced experience, where the dominant sense is vision.

Nevertheless, what is happening in the digital realm? How sensorial experience is amplified when the subject is isolated in front of a computer screen? The answer to both questions is associated also with vision. The “thing” is formed in a process of “becoming”, a design process, and it can be read and interpreted always in relation to the quintessential conceptual term required by the design tools; the request of obtaining presence through representation (figure). An interesting example is the work of Lionel March, mainly in the context of the link between instruction and interpretation. Typically, March attempted to render interpretations to the built architecture through acts of the Boolean Operations Binary System 1-0. (March, 2010).

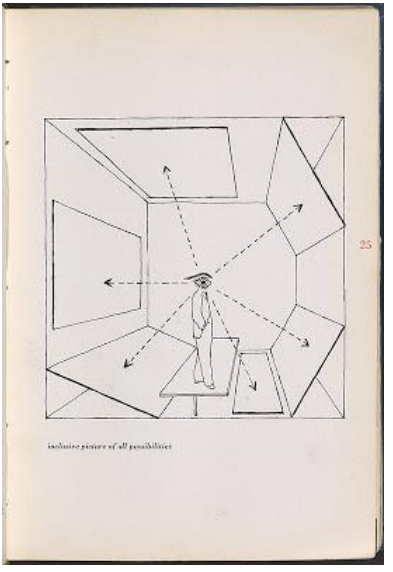

Figure 2. Extract of the Mnemosyne Atlas of Aby Warburg (1930).

Figure 3. The curatorial mechanism by Herbert Bayer (1930).

Hence, idiosyncrasy enables understanding of common principles and rationales within a given time and cultural context and helps us to synthesize trends and theories, which describe forms and "spatial productions" of the main elements used to characterize them. Forty years after J. Habermas's theory of communicative action and N. Luhmann's systemic theory, A. Reckwitz formulates an original theory of late modernity referring to the distinction between particular and general in culture, digital technique, and lifestyles, introducing the notion of uniqueness. In this society of uniqueness, which is described as the modern society that revolves around the pursuit of uniqueness both in objects, in subjects, both in space and in time, idiosyncrasy can become a tool to construct collectivity. To be able to properly describe this constructing process we introduce a digital idiosyncratic methodology, which will record, archive, categorize and interpret the subject's idiosyncratic expressions during a real-time design process, within a digital design software/environment. This methodology allows a "dissection" in the design process itself, while at the same time offers the possibility to redefine the design and its implementing instrument; the design program.

1.2. I (eye) – valuate

Although idiosyncrasy is enabled by desires, fantasies, and immaterial interpretations of the real, it leaves traces that can be read and measured. Thus, the triggering object of

idiosyncrasy, which we name “idiosyncratic object” is an unattainable object; an object that escapes perception. Our goal is to try to create a system of understandings for the idiosyncratic object. This object, which we name ID-Object, can be grasped by reconstructing the many different frameworks to which it can be exposed, displayed, and exhibited. When exposed, the ID-Object is viewed in a raw state of/for use. When displayed it requests the condition of a filter between the ID-Object and the Subject-Viewer. While exhibited it becomes an Object-of-Value. Through all these states a new system of relationships emerges; relationships of transition are released by the narratives that the Subject uses to “dress” the ID-Object so that it becomes attractive. To describe this complexity, we focus on the tool of the diagram, which becomes a medium of presentation for the relations that arise. Hence, the ID-Object is converted into a field of interpretations that reveals the idiosyncratic imprints of the Subject.

Via this context, we can extract the value of the idiosyncratic object, and, subsequently, we obtain the possibility of detecting and describing its characteristics. Thus, there are three modules of value in the design process: theological materiality, the everyday object, and the time(less) cultural object. These modules of value re-establish the conceptualization of the framework of the idiosyncratic object; it shifts towards historical materialism and closer to an idealistic/fantastic/imaginary approach to the idea of history.

Therefore, idiosyncrasy obtains a functional role as it produces an intermediate space within the relationship of Subject and Object. Therefore, as the Object gains a multitude of interpretations and facets, at the same time the Subject gets endowed with multiple roles through its socialization, becomes multiple, and is transformed into a field. This multiplicity affects the empirical process of understanding the system of objects that comprises its environment, in a way that differs from previously established theories. Hence, idiosyncrasy works in a subconscious way that contrasts with the systems of perception and the rational methods of the Gestalt theory.

Here’s an example: I see a director's chair or a mug or every-day object, in a warehouse, in my home, in a museum, in an online shop, and so on. As I attempt to describe the subject as a whole, experiential associations are created (Hamilakis, 2014, p. 29). Images are retrieved from multisensory memory forming a web. The relationships between them also create meaning - the hyper value of the object itself. Thus, perception with its multiple views, associations, and metaphors creates a system of interpretation, which enables a process of interaction. I see a stimulus, I perceive it and interact with it (buying, using, and designing) and eventually, I am led to a meaningful construction of multiple subjective views and idiosyncratic associations. All these metaphors create an idiosyncratic value system. Moreover, the tools used in the process of perception can be also used as tools for interaction, where understanding manifests the minimum expression of interaction.

Back to the design process, an important field to study is the transition from engraving to the design process and from drawing to design production. In other words, the study of

communication and description, through the process of material-immaterial translation, and how it yields the expression of the subjective "vision" of the designer. At the same time, the process described above is also involved in the transmission of design knowledge through different regions, epochs, and cultural backgrounds.

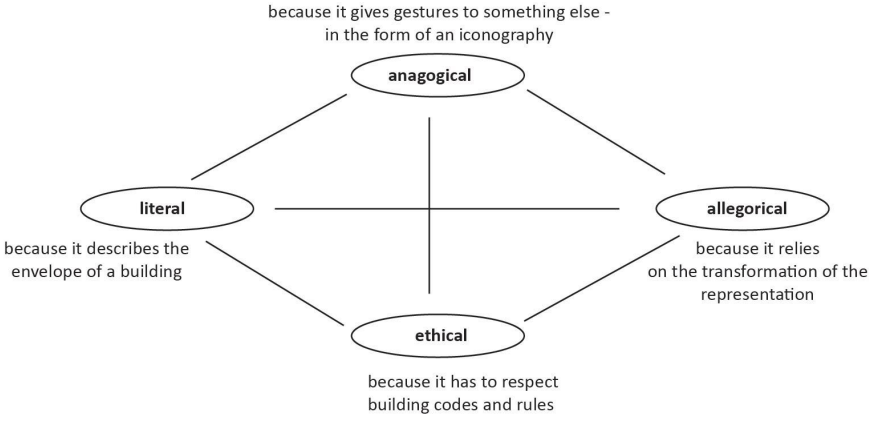

Figure 4. The four senses of Paper as an interpretation of Paper according to M. Frascari.

Marco Frascari, studying paper as such a condition, and at the same time in conjunction with the invention of typography (Frascari, 2017, pp. 23–32), uncovers the four senses of design (Figure 4). If we extend these senses to digital design, during the transition from analogue to digital the reduction is lost (anagogia). Anagogia can be traced back if we “capture” the relationship between a designer (user of the program) and the creator of a design program in an imaginary piece of paper. Via the medium of the tracing paper, the architect prepared a "sotto Lucido", that is, an underdrawing, where one can then draw the Lucido on top of it. One way that the concept of transparency as an intermediate space could be applied to digital design is a research area for the present work and will be further discussed below, as well as the design of the very transparency itself. Therefore, we understand that the design of an intermediate space is also a practice of meta-evaluation. What follows next is a series of other practices: the creation of uniqueness and the creation of intimacy. Uniqueness is experienced emotionally, as a sense of the sublime, of harmony, enjoyment, admiration, fear, pride, and so on, either bi-subjectively or solitarily (Τάσης, 2019, pp. 159-175).

2. The Unseen in Design

What is the value of idiosyncrasy for the Subject-Designer? Is this value constant both in an analogue and digital process? Diagrams as interpretations, introduce tools for measuring value?

In the synthetic phase of design, we refer to a “hypertextual” process that attributes the basic properties of the logical description of the design (in-port). When an object is interpreted performatively in an in-display condition, it is destabilized and transformed (ex-port) into a cultural symbol. But how can these two readings be correlated? The terms "import" and "export" are transferred into a new conceptual spectrum as "in-port" and "export". The reason is that we are trying to examine in depth the two fundamental processes of (digital) design, namely its start and completion.

The question of why architects choose programs (ready-made interface environments) to create, instead of choosing to design spatial relationships, conditions, and constants in a single programming language is a starting point. This question underlies the problem that we are planning by evaluating one export rather than a multi-export network. We see the representation/form of what we want to draw in a frame, in a picture instead. So what we design is constantly modified one-dimensionally by the image through the interface. But what is it that we do not see when designing? In Figure 5 we can see the "space" in which "what" we are designing is conceptualized by monitoring the invisible by-products of a digital design process. (Figure 5)

According to the diagram below, it is understood that there is a "latent" design in the design process itself. There are a basis and a system that allows us to "enter" and add our expressions. So, going back to the ratio of tracing paper, the design program is a Lucido on which our temperament carves out its own sotto Lucido, but which we can explicitly identify and highlight. To do this, the digital measurement methods of design temperament we propose are the following:

1. A Digital Interview, through the creation of a pop-up plugin, which will appear on the user's screen with a short questionnaire asking the reason of choice of the action-section made while designing.
2. Recording and interpreting those elements that are not immediately visible in (digital) design by:

- The use of the MouseTracker program to create a heat map of the subject's designing paths.
- Recording (quantitatively and statistically) not only the number of errors (via the Delete and Undo commands), but also the multitude of copies and alternative versions of files and designed-objects the user creates.

Thus, what we propose is a monitor device that captures the logic of the program, by supervising how it establishes and transforms the invisible space between the user-designer and the in-design object.

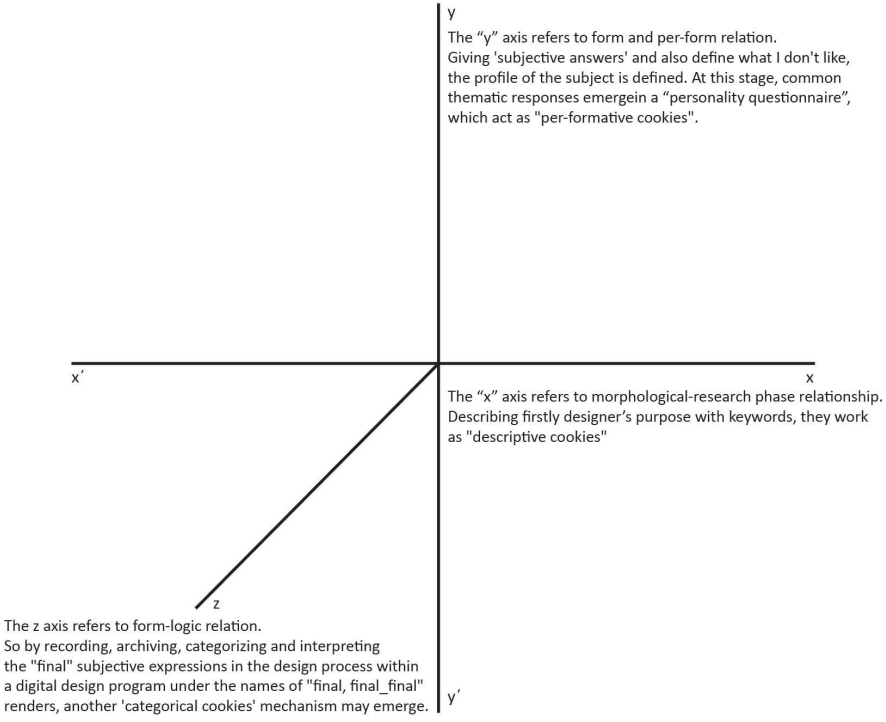

Figure 5. Space-making / poetics of space condition diagram of an algorithm recording the unseen by-products in a digital design process

2.1. Inter – View in Design

The first step of our study refers to a recording of the design context a Subject-Designer creates in actual design software. The testimony of such recordings derives from highlighting the subject's uniqueness. Uniqueness enables singularity which can be defined as the merge of biological and technical evolution (Τάσης, 2019, p. 28). This process reconstitutes a different understanding of the idea of an interview. In our research interview becomes performative; it provides and surpasses general identification data (such as sex, age, etc), by focusing closely to design preferences that are highlighted through technical evidence (geometries, materials, processes of assembly).

What we observed is that etymologically "interview" withholds a performative and collective vector. It brings together Subjects in a meeting/festive/happening condition to create (new) knowledge. We emphasize that the importance of the interview allows the quantification of user-designer data, from which we can draw - through repeatability - qualitative conclusions about their modality; the way designers design. Thus, it gives us a more penetrative view

into the soul of the designer. However, it is important to note that we are not talking about an interview in the traditional way, where the journalist asks questions to an interviewer and expects answers that are recorded or documented. In our research a "translation" takes place. On one hand, the role of the journalist is replaced by that of the investigator, and on the other, harvesting of the temporal moods of the designer becomes palpable and accessible.

If we further elaborate on the performative side of this interview we can gain access to "pre-positions" of the Subject-Designer. These pre-positions refer to all these genetic principles that establish and institutionalize the manifestation of a design act, and they serve as a key to gaining access to the idiosyncratic status of the designer. Therefore, a dual nature is detected in the designer himself; in addition to being a designer he is also a user, and as such he can be examined for the causality of his actions while using the specific syntax of actions that legislates the design software. Consequently, what is permitted and enhanced is the gain of knowledge of idiosyncratic design methods produced during the real-time design process. In particular, by asking a question, while designing and not after or during a break, a kind of "shock" is created in the quality of the interviewee's response. It is a form of "epiphany" not in its theological complexion, but the anthropogenic and deeply intrinsic aspect of the subject.

Therefore, the randomness of the interview turns into an “idiosyncratic snapshot”, which aims to elicit answers from one or more users of a design program. It is an infiltration into the subconscious, inner thoughts of the subject-during-design; those thoughts that only an immediate "why?" can shock and respond with both immediacy and "purity".

These interviews, to be real-time, must have some trigger (triggering actions). These activators are characterized as cut-outs because they stand out from all other operations that are repetitive, purely mechanical, or have to do with improving the productivity or modes of displaying objects in their digital dimension.

From the example of Autodesk AutoCAD and how its interface commands-acts are categorized, we can immediately conclude that over the whole range of this program, fundamental genetic design acts are summed up in a set of 50 commands, which are called "operations-cutting points", because they produce something new, by transforming the existing under-design object through idiosyncratic intentions that push the subject to perform. These are just two subcategories with about 20 Draw commands and another 30 Modify commands. In our research, we are interested in establishing the primary definition of the designer’s idiosyncrasy-measuring program and distinguish all idiosyncratic answers from the ones that have legislative or other technical constraints. The purpose is to comprehend the questions in detail and to determine when and how they will appear in a small window on the interface of the program used by the designer (pop-up window with feedback). (Figures 6, 7)

An example would be:

Q: Why did you choose to make this Fillet? (Note that for example, this fillet may have a very large radius)

A. Aesthetic Answer: I want spherical outlines that do not have sharp and aggressive angles. I want the shape to soften and become more organic so it can blend with the environment.

B. Technocratic Answer: I want all corners of my plot to allow large objects to rotate.

2.2 Design the value of MEmory

Beyond the speed of computing, interconnectivity, openness to knowledge, and many others, one of the greatest and probably the most important virtues that the computer has brought to our daily lives, but especially in our way of thinking, is that of "going back in time; recalling and correcting an error. In a computational environment, it is possible to press the undo button and erase an action without having to bear any consequences. This allows us to try and experiment up to the point where the program can write in its memory the history of the actions of the user. In our case, our interest focuses on identifying if and to what extent it is possible to operate alongside other programs that will be able to collect design-related data in digital design software. What interests us is data that refers to the way and to the duration of usage of the design software, as well as data that indicate repetitions and "errors" in the design process.

An example of this ability, to export real-time usage data, is the program[1] "MouseTracker" developed by Jon Freeman (Freenan, 2020). Through the transition from the non-descriptive of the unseen side of the design to the descriptive one, through the designers' footprints in real-time, the design in its entirety produces a multiple-subject (subject-designer-user) tank. Thus, a whole new world opens up in how we can recognize and study the uniqueness of each individual, simply by measuring how he designs, molds, and archives. However, this is an undergoing process of our research and it will be developed in the future.

[1] Indicatively, we mention other similar programs, such as Mouse Monitor, MouseFlow and MouseTrap-os. On the latter, see (Kieslich & Henninger, 2017).

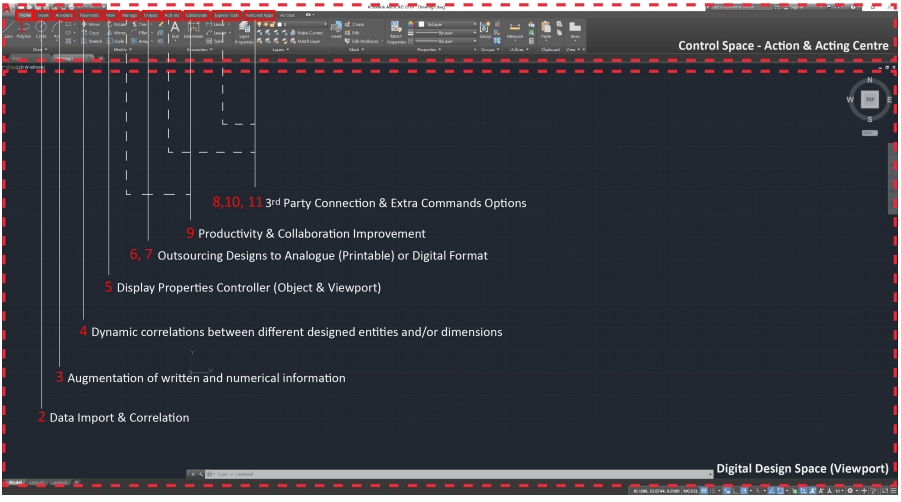

Figure 6. Digital Design Viewport as a framework for applying the idiosyncratic performance in design. Classification of commands and their signification as realization processes. Processes that embed properties into "That" that is under the design process.

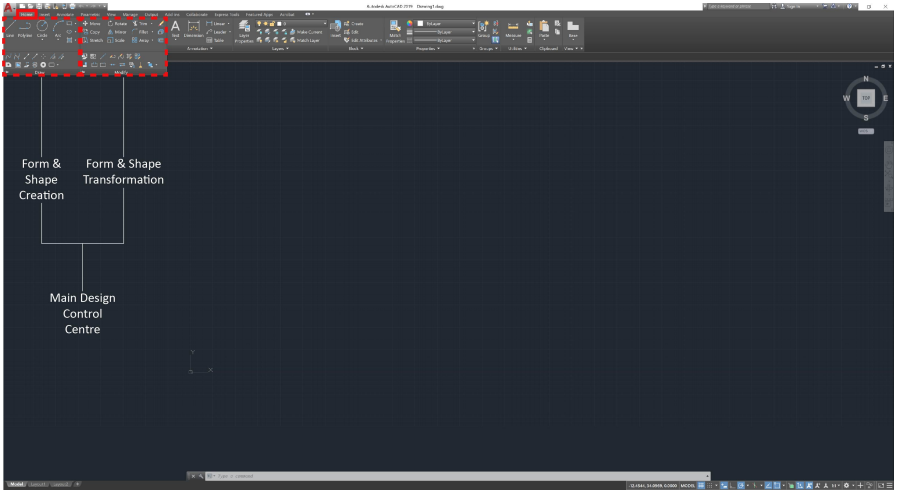

Figure 7. The main menu of Morphological processes. Their interpretation as objectification processes. Procedures for the emergence and application of "idiosyncratic" logic.

3. From ontology to ontological form

If we think back to what our mechanism ultimately produces, we could probably say that it captures, transforms, and expands the Subject-Object interface in digital design environments. We map the intermediate and bring out the uniqueness of each subject by extracting memory from the physical (digital) evidence, not only from their actions but mainly from their intentions. Such a proposal, an algorithm recording unseen parameters during design, is a development of the design language vocabulary within the existing digital design environments.

Therefore, an ontological identification map of the post-designed object is produced. The user has the choice to intervene on this map without the actual object being visible, drawing it in an ontological context. And then there is the command that transforms the ontological map into an image. These images are the reflection fields on the original object. So, what is produced? A time gap or otherwise a dialogue between the designer and the object.

Moreover, one result is the design of the framework in which our temperament is more freely expressed. We do not define freedom as an arbitrary and meaningful concept that comes to fill gaps in our study. This freedom depends on the degree to which we can narrow the boundaries of design software to do things out of context. The result of such a process will be to create a new structure in the hub of forums that the design software already has, and where the users are looking for solutions to problems or improvements to existing and incomplete commands. Such a forum will not only send analytics and feedback to the design software provider/company but will be essential for further conceptualizing the Subject-User. In other words, it is a meta-forum, more immediate, personal, and practical.

Finally, a reflecting point of the outcome of this idiosyncratic plugin is the importance of ethics in such a software, which is based on the sincerity and validity of the subject's responses. This is certainly its “Achilles heel”, but not a manufacturing mistake. This condition is the "necessary evil" to grasp the importance of the outcome of this software in design. The inability to create social meaning and the introduction of new values have contributed to the emergence of the life-craft industry (Τάσης, 2017, pp. 83–117), where the question of meaning arises in individual terms. Guided towards a narcissistic collectivity (a reflection of society), self-realization, and the acquisition of design confidence through exposure to and acceptance by design collectivity, this specific plugin, by giving the choice of true/untrue answer, ultimately might work reflectively on the Subjects themselves, as a view of emancipation.

About the Authors:

Angeliki-Sofia Mantikou is an architect-researcher and Ph.D. cand. in NTUA. Her research field focuses on interdisciplinary, idiosyncratic methods between art and architecture. Her practice extends from architectural design to participation in art exhibitions (14th BJCEM, 2011) and curating.

Athanasios Farangas (1987**,** Athens) is an architect-engineer and researcher. He practices architecture at Coop Himmelb(l)au and pursuits a Ph.D. at N.T.U.A, focusing on the comparative intersection of Architecture & Computer Science in digital design software.

Theodoros Zafeiropoulos is a visual artist and assistant professor in NTUA, School of Architecture. Since 2001 he has presented 10 solo shows and has participated in more than 100 international group shows, residencies, and projects in Greece, USA, and elsewhere.

Alexandros Psychoulis, visual artist, professor of Art and Technology at the Department of Architectural Engineering of the University of Thessaly, head of the Postgraduate program "Post-industrial Design / Design and artistic practices for the production of everyday life" of the same Department.

Acknowledgements: Special acknowledgements to Professor Mr. George Parmenidis, Prof. of the dep. of Architecture NTUA, for his lifelog companionship and mentoring. “This research is carried out / funded in the context of the project “I-D (I – Design, Idiosyncratic Meta Design) Idiosyncratic Proceeding on Reading and Production Meta-Objects in Contemporary Industrial Design” (MIS 5049532) under the call for proposals “*Researchers' support with an emphasis on young researchers- 2nd Cycle*”. Abstract | The culture of making has always been seen as an inseparable part of design. Still in recent years we have witnessed that "making" gets less and less attention (i.e. time and resources) in our design education. The reasons for this are manifold. Among others, it reflects developments within the evolving field of design, as described by Bremner and Rodgers (2013). In contrast to this development, we argue that the action of making remains an utterly valuable part of design education – a valuable linkage of knowing and doing (Ingold, 2013). As an alternative, we propose to advance the culture of making, its inherent focus and assumptions instead of neglecting them. This essay presents insights and reflections of a collective exploration into making by four design educators and practitioners. The collaboration happened in different settings, sometimes with other local actors, was always guided by constraints. During the research, questions of how design education can facilitate meaningful learning processes around making, while not ignoring the evolving field of design were explored. The result addresses the complexity of co-creation, dialogue and practical knowledge in the setting of a contemporary design education.

KEYWORDS | COLLECTIVE MAKING, CREATIVITY, PRACTICE BASED KNOWLEDGE, CHANGE

1. Introduction

The culture of making has always been seen as an inseparable part of design. Still in recent years we have witnessed that "making" gets less and less attention (i.e. time and resources) in the design education we teach at. The reasons for this are manifold, but we don't think they are unique. In our particular case, the driving force has been a concern to orientate design towards a less materialistic, and in result less wasteful practice (Findeli, 2001; Tonkinwise, 2003) and to focus on the role of designers as researchers and facilitators. In addition, the aim to develop a critical view on designing, to explore dissolving disciplinary and conceptual boundaries which paved the way for new and multiple ways of practicing design (Bremner & Rodgers, 2013) as well as the effect of establishing design education within academia and its rather logocentric knowledge traditions have all played their part in this development. At the same time, the rise of 'design thinking', too often highlighting only 'thinking', has also enhanced the distinction between thinking and practicing design, instead of "acknowledging the situated, embodied work of design thinking in practice" (Kimbell, 2011).

In contrast to this development, but not in ignorance to it, we argue that the action of making remains an utterly valuable part of design and design education – a valuable linkage of knowing and doing (Ingold, 2013) – that deserves to be cared for. As an alternative, we propose to advance the culture of making, its inherent focus and assumptions instead of neglecting it. This essay presents reflections of a collective exploration into making by four design educators and practitioners. Our goal was to explore "making" in an explorative research project, addressing the complexity of co-creation, dialogue and practical knowledge within the setting of a contemporary design education in reaction to situations we experienced as the "theoretical turn", allowing theory to dominate practice – or even render it irrelevant. Our work was inspired by the idea to create a form of seminar series around making. Instead of focusing on a theoretical piece of work, and exploring it through discussion and dialogue, we focused on recurring meetings around a particular task or material and explored it through practical work.

2. The making of our worlds

2.1 Our context

Our self-initiated research project was set up in the context of a rather broad design education that abandoned disciplinary boundaries a long time ago. As a consequence, our educational situation differs from design educations with an outspoken focus on a particular discipline or material. But at the same time, our education is based in one of the few state-funded educational higher institutions in Sweden that are allowed to award a degree of Fine Arts at both bachelor and master level. For this degree, the Higher Education Ordinance defines that students need to show evidence of both practical and theoretical foundation, to

demonstrate the ability to create, realise and express their own ideas and to undertake artistic tasks. Artistic education, like artistic research, has artistic practice as method and as knowledge object (Lilja, 2015) and assessment is closely tight to the idea of artistic quality, which can be summarized as technical craftsmanship, material skills, personal expression and a relevant process methodology (Karlsson Häikiö & Olsson, 2015). As teachers, we therefore have to strive for a balance between the theoretical and abstract and the practical, concrete dimensions in a way that supports this development.

Our project was an attempt to explore and develop making not from an individualistic point of view (how to improve one's individual skills), but from the perspective of educators and collaborators in a wider context of making. It was meant as a challenge to reflect on our own knowledge around making and to test new things – before we bring them into the classroom. Last but not least, we hoped it might offer a dialogue around making and its role in the curriculum. Contemporary demands on designers differ widely from the traditional ideal of being a skilful craftsman. Still the ability to make something real remains essential and as influential as creativity in the world of design (Nelson & Stolterman, 2014).

2.2 Making

> "I want to think of making instead, as a process of growth. This is to place the maker from the outset as a participant in amongst a world of active material. These materials are what he has to work with, and in the process of making he 'joins forces' with them, bringing them together or splitting them apart, synthesising and distilling, in anticipation of what might emerge." (Ingold, 2013)

Making has been central to our project. In design and craft, making can be defined as the skill, experience, and mastery of working with material and/ or processes (Design dictionary, 2008). "Making" as a verb refers to action and process and is more than producing an artefact. It can be a teacher, a process of growth and an inquiry into the world (Ingold, 2013) or "thinking" (Sennett, 2008), supporting exploration, understanding and discovery.

The field of making has changed and expanded its role in society during the last decade. In the agricultural society people used making and crafting in their everyday life to make the objects they needed – for their homes, for cooking or farming. During the industrialization in the 18th and 19th centuries, making became something a craftsman did. Artisans or industries made objects for everyday use, or exclusive items of very good quality. Crafted pieces could also be seen as art (Bringéus, 2005). From the 1990's onwards status of making became low as people started to work digitally. Craft seemed boring, unnecessary, and unfavourable in the process of establishing academic and professional legitimacy for design (Design dictionary, 2008).

Today we can find making again in many contexts. The maker movement has grown widely (Anderson, 2013), craft bars and craft clubs with the aim to make craft together and socialize with others have become popular, as well as knitting cafés and craft pods. Their aim is rather to make, learn and have fun together, than to craft high quality objects. As an offspring to

this development, making is also seen as useful for people's wellbeing and as a kind of stress relief activity (Davidson & Tahsin, 2019).

Another field of the maker movement is craftivism. People use craft as a form of activism to make a statement on political and social topics. By making embroidery and showing them in public spaces, people try to affect and change societal development of society (Corbett, 2013; Arnqvist Engström, 2014; Greer, 2014). On the other end of this spectrum are handmade objects of high quality with a comparable status to art, that are shown in shows and fairs like for example Collect, a gallery-presented art fair dedicated to modern craft and design. The handmade object is valued as more authentic, more real, than machine made or digitalized work (Design dictionary, 2008).

The culture of making has always been seen as an inseparable part of design, but both in society and in education the role of making has changed. The authors Press and Cusworth (1997) fear that in the general opinion craft has little or no educational value in our post-industrial, information centred age. It seems to embody all those qualities that are considered irrelevant or inappropriate: individualistic, self-centred, low on technology, and with little contextual or critical context (Press & Cusworth, 1997). In addition, concerns regarding designs damaging and wasteful practice have questioned the need to make (Fry, 2009; Tonkinwise, 2003; Findeli, 2001).

> "This, in turn, yields to the end of the "product as work of art" paradigm in design, and of the design act as a heroic gesture; in short, the end of the fetishism of the artifact." (Findeli, 2001)

But the criticism against making often refers to what is brought into existence, and is less concerned with what the activity entails. Design education can still view making as a useful tool for exploration, visualisation and finished objects. Making workshops are organised for different reasons, either as introductions to new fields of making, or to give people with different backgrounds possibilities to explore and work together. In the field of speculative design, crafted objects of high quality are used to convince the audience that the design proposal is realistic.

In our research project we have used collaborative, artistic making. Each member of the research group has contributed to the research with their professional knowledge around making as designers, artists and artisans and shared their knowledge in different materials, methods, techniques and processes. In an exploratory form, we have tried materials and contexts new to the individual, by using the whole groups practice based knowledge. We have tried our working method in different projects for more than two years.

2.3 Design and the nature of knowledge

There is no simple or ultimate answer to what design is. As a field it is constantly evolving and boundaries of what were once recognised as individual design disciplines (such as product, graphic, textile, and fashion design) change, dissolve and expand (Wilson &

Zamberlan, 2015; Bremner & Rodgers, 2013). As a consequence, it is impossible to speak about design education as a unified or even static concept. Still the design researchers Nelson and Stolterman (2014) suggest that the learning outcomes of design education are a set of interrelated competencies (mindsets, knowledge sets, skill sets, and tool sets) that relate the abstract epistemological (thinking/ knowing) with the ontological concrete (doing/ acting/ making). While there is definitely a general understanding that shaping and making are part of design, questions regarding content, focus and importance remain. The activities of making, shaping, doing and even acting are as multifaceted and evolving as design itself.

Many things that could be said about design education. One aspect relevant to our work, is the intuitive nature of knowledge. A study by Karlsson Häikiö and Olsson (2015) suggests that the academic demand to formulate practical knowledge within academia clashes with the fact that artistic knowledge often develops through the unknown, undefined, and varying (Bauman, 2002, as cited in Karlsson Häikiö & Olsson, 2015). As a consequence, design teachers in their study experienced the assessment of artistic processes within the academic setting as antithetic and conflicting.

> "Within art and design education intuitive modes of learning and doing are very important … under various labels (tacit knowledge, implicit knowledge, non-verbal learning, learning-by-doing etc.) these intuitive modes may be very resistant to analysis or conscious awareness but are central features of practice and learning in the arts and in design." (Danvers, 2003)

But the conflict goes deeper than that. A logocentric culture sees knowledge as something that can and needs to be articulated in precise words. In extension, it doubts other forms of knowledge which affects how education is shaped.

> "Current theories of learning typically emphasize cognition and the mind, rather than embodiment of mind and self. A consequence of seeing mind, body and world as separate entities is that the significance of our entwinement with the world of practice is overlooked." (Dall'Alba, 2009, as cited in Adams et al., 2011)

Especially in design those different knowledge traditions collide - the practical knowledge tradition with its roots in experience and practical work and the theoretical knowledge tradition with its roots in research, concepts and theory. Nelson and Stolterman (2014) emphasis that the integration of thought and action in design sets it apart from other disciplines. And the authors Press and Cusworth (1997) suggest that intelligent making "a mix of formal and tacit knowledge, physical and mental skill, theoretical and contextual awareness, innovation and personal creative autonomy" is able to convey new styles of thinking, acting and problem solving, which might be more suited to our changing world. All in all, making connects back to a dimension that should not be given up on easily.

3. Our Research

This essay focuses on two years of seminars and work around making. Two particular design tasks were done in collaboration with local actors; the design of an insects shelter for a local urban farming initiative and an artistic project around industrial waste. Especially in this project we looked in depths into the waste materials origin, their journey, related issues and used making as our research methodology during the course of roughly one year. In between those tasks, we engaged in smaller projects in which we explored different materials and techniques, and reflected on our experience afterwards.

Our research can be described as practice-based (Candy & Ernest, 2018), an investigation in order to gain new knowledge partly by means of practice and its outcomes. We embarked on it in a collaborative way, emphasising our professional development rather than hoping to generate new theory or knowledge (Clark et al., 1996).

Our research was organized in the following way: One-day workshops started always by the presentation of the task though one member of the group, followed by approximately 6 hours of working time. The reflection happened several days apart, in the form of conversations and a written documentation. The larger projects started by on-site and industry visits and material explorations through one-day workshops. Subsequently we tried to find a story in the material or place. In the idea generating and sketch phase the practical work was interwoven with reflection and discussion meetings. The methods used to document the work were photography, individual notes and sketches as well as all three-dimensional traces of the process like mockups, material experiments and moodboards. In order to evaluate our work and to identify the learning outcomes of the entire project, we summarized individually we felt we had learned and experienced during the project. The goal was to relate those findings to the educational situations we find ourselves in and if possible to develop ideas on how to advance it.

Our most time-consuming part was a project that resulted in an art installation called “Waste camp”. The installation consists of a tent, a fireplace as well as relevant equipment. We chose camping as a theme as it represents both the aim to be close to nature as well as shows how this is choreographed by numerous artefacts that rather reinforce our separation. This duality was also present in the waste we had at our disposal. All materials had once thrived as part of nature; still humans had spared no effort to transform them into an artificial state. While our work was always guided by constraints, it was most dominant in this project. We allowed us only use waste material from three local industries. One producing high-end furniture, one matches and one manufactured everything from gaskets, sound absorbers to insulation and furniture components to supply various industries. The majority of the material would usually get discarded and most likely burned. We tried to develop a concept that was true to the origin of the material. Our aim was to create a new and different context for industrial waste in which its value is emphasized by treating the material with care.

Figure 1. Waste camp – the final result. November 2019.

The result gives on one hand tangible form to our collective knowledge around material and making. It is characterised by what we already knew, what we learnt and what the material made us do. As a material result it is left to the mercy of the spectator and the question if it qualifies to the standards of creativity, ingenuity and aesthetics, as well as if it as a symbolic representation of an idea affords to "be interpreted within the hierarchy of constructs and degrees of abstractness imposed by its cultural context" (Press & Cusworth, 1997). At the same time, the entire project is a document of a process and a conversation around collective making. In the process we had to articulate and discuss our making in order to collaborate, and to drive the process further. We had time to elaborate about how our work could translate into an educational context and what would be important to consider. Reflections we will try to share in the following text.

4. Reflections – a manifesto for making

4.1 Glue guns and post-it notes are not enough.

> "A conceptual idea is not worth much if it is not made manifest in the world."
> (Nelson & Stolterman, 2014)

Making is the ability to translate ideas into this world. As this, it is a highly complex activity

that connects materials, skills, tools and methods to a reality. In our projects we needed to respond to limitations, show resourcefulness and the ability to improvise, understand complex realities and networks and work with care towards materials and tools. We had no idea about the final result before we started, and despite sketches and models, the work developed constantly throughout the process. Much of the discoveries and learning happened physically and through tangible interaction. As Nelson & Stolterman (2014) highlight 'wise crafting' nurtures and matures a design idea and is also characterised by the carefulness of the process itself.

Figure 2. The process of preparing the floor. September 2019.

In education we nowadays engage often rather in forms of "speed making" – with post-it notes and glue guns as main ingredients. "Speed making" is quite often similar to brainstorming and works well to start or to swiftly focus in a longer process, but is deprived of knowledge about material, construction and production and other constraints that eventually need to be addressed in order to make something real. Still all making is a good beginning, if it is communicated to the students on what kind of level the making is happening and what other levels could be there.

4.2 Material carries a narrative.

We do not ignore the criticism against making. The industrial waste we worked with was brutal and real proof. To see material turned into objects that people use is one thing, to see it turned into useless waste another. Waste has consumed natural resources, energy and water for nothing. But the waste we encountered was not solely an unavoidable part of industrial production, it was also the result of rigid quality assurance and fashion. Within high-quality products, insect bites, butcher mistakes and small changes in structure can for example render large parts of leather useless. We also received large quantities of spotless

material which only fault was an unpopular colour.

From this experience, we draw the conclusion that making is always part of complex systems and should be taught like this. Making is not only the skill of creating something with a certain level of expertise, but an array of knowledge connecting it to entire systems and a context in which the making takes place, including values and norms. By avoiding to work with making in education, we avoid the chance to evoke reflection and a deeper understanding for this. Instead we foster consumers by impairing the ability to create by oneself.

4.3 We create in order to understand.

As a research group we got the opportunity to work collaboratively on artistic, practice-based projects. The projects developed in a way that none one of us could have achieved alone. In the end, all skills and efforts were needed to connect to the industries, to collect the material, to explore and create and to articulate the concept and the project in its entireness. The group multiplied our possibilities. To take part in a creative process can be fun but also challenging, not at least when you are working in a group. The most prominent in our own evaluations are reflections regarding the group process and how it had affected the process and result. Did we actually make the best use of our abilities? Several aspects of the artistic process, the idea of an individual voice, individual interpretation, creativity, trusting the process, intuition do not lend themselves perfectly to group processes. Conflicts do not only arise to push for one's own idea, but to make an idea coherent. Moments of 'flow' and 'anti-flow' appeared at different stages, caused by different opinions on the process or expected outcome, but also by stress and different working methods. "... we all know how tough a conversation among peers - particular designers - can be, each one defending his/her culture, experience and belief" (Devecchi & Guerrini, 2019). We realized that clearer communication in all stages would have made the creative process more enjoyable.

4.4 Experience, our own and others', is the basis for innovative practice.

Working in groups is becoming more relevant for designers (Wilson & Zamberlan, 2015, Sanders & Stappers, 2013) and as a result it becomes important to address collaboration and collaborative skills in education. So far, we often underestimated the demand for facilitation that group work places on teachers and students. How can we prepare students and support group processes in the best possible way? How can we balance individual artistic development and skills that benefit group work? How can we evolve values and methods that are still influenced by design as an individual activity?

This research has had a transformative approach as it sharpened our awareness and made us critically reflect on our assumptions and ways of teaching. In the project we used our knowledge about material and practice in different ways than we usually do as educators, which helped to illuminate our habitual ways of working, communicating and making

judgment. We experienced the competences and skills of colleagues in new ways and subsequently developed an understanding of our own skills and took responsibility for being a good collaborator. While the dissonance between practical and theoretical; situated, embodied and abstract will persist for a while, we need to continue the dialogue, as not speaking about its value is damaging our own situation. “Inarticulacy gets mistaken for a lack of knowledge and an inability to rationalise actions.” (Press & Cusworth, 1997)

4.5 It takes time.

And finally, making and refining skills takes time. Due to an increasing complexity of the design field, this of course raises many questions. Within the education we teach, it was never an official strategy to eliminate making and practical work, rather making was taken for granted, while in reality other tasks demanded more and more time and attention. At the beginning of our research, we often accepted that making received less and less time. By the end of it, we had managed to make this an issue within the department and achieved partly to halt this development. Still, in the future, we will need a continued dialogue around making and its relevance.

5. Conclusion

We still believe that the action of making remains an utterly valuable part of design education and culture – a valuable linkage of knowing and doing (Ingold, 2013). Making is a way of understanding and exploring the world with all senses, as well as a mode of action in dialogue with the world, but making, as an activity beyond post-it notes and short workshops will continue to be a time-consuming, exhausting and complex activity, always in danger of being rationalised away.

Our collaborative journey has deepened our own understanding and given us time to explore making in various ways. The times we live in demand us to discuss what we see as the material of design - physical as well as abstract - and what the craft involved in the production process actually is, from a broader perspective than the traditional practice of material design (Nelson & Stolterman, 2014). But nevertheless, if we act through making, doing or acting – as they all are of relevance for design – we should treat them with the same care, ingenuity and skilfulness as wise makers always have. If we can’t make it together, we won’t make it alone.

About the Authors:

Lena Håkanson is a senior lecturer at the Department of Design at Linnaeus University. She also works as a freelance designer and workshop leader. Her main research interest is practice-based knowledge and making in the field of textile and print.

Stephanie Carleklev is a senior lecturer in Design. Her research interests cover design research, visual communication theory and practice, and how design education can support students to engage, persist and succeed in becoming inspiring and caring design practitioners.

Stephan Hruza works as a teacher at Linnaeus University. with practice- and material-oriented courses. He is a furniture designer and cabinetmaker. His research interests lie in practice-based knowledge with a focus on sustainability, materials and reuse.

Anna-Karin Arvidsson works as a senior lecturer in design at Linnaeus University. She also works as a ceramic artist. Her main interests are artistic based knowledge and materials in relation to identity both from a human and material perspective.

Abstract | Knowledge of Culture and History is a very important component that dictates Design and it is from our past that we learn and create for the present and the future. The question facing Design educators today is how to align the present generation of millennials with the sensitivity and appreciation of our rich cultural heritage? The paper is focused towards the Future of Design Education, by stressing the need for the knowledge of Culture and Crafts as an integral part of Design Education that will help the Designers of tomorrow to be prepared for the Future. According to the authors, simply sitting in the classroom or searching online cannot help students learn about Culture and Heritage. To experience culture one has to actually go out into the field, dirty their hands and gather first-hand experiences. This will, in turn lead to a better understanding of the issues and challenges that present themselves to a Designer in the course of their Design journey.
This paper examines ways in which these qualities and skills/knowledge can be nurtured, with a specific example of an Interior Design course in India. Based on literature study and their findings from student assignments, the authors believe that Design Education should aim at sensitizing students about the cultural heritage and provide them with avenues and exposure to explore their cultural and contextual backgrounds as they are the future custodians of their culture.

KEYWORDS | TRADITIONAL CRAFTS, DESIGN EDUCATION, EMPATHY, HERITAGE, CULTURE

1. Introduction

> "Without culture, and the relative freedom it implies, society, even when perfect, is but a jungle. This is why any authentic creation is a gift to the future."(Albert Camus)

Knowledge of Culture and History is a very important factor that dictates Design and it is from our past that we learn and create for the present and the future. Cultural traditions and crafts along with the knowledge/skills form the cultural identity of a people.

In India, Traditional crafts have been an inherent part of the process of making. Such processes are organic and involve traditional knowledge of socio-cultural and religious needs, climate response, geography, local materials and the particular context in which they are located. All this collective wisdom has been handed over from one generation to the next as a legacy. It is seen that culture has an important place in the psyche of a community, in fact, a reflection of their identity and their histories, forming a composite whole that has many facets: social customs and mores, religious practices, language, food, shared histories and memories. India has a vast storehouse of traditional crafts, and almost each one of these crafts comes with a deep sense of history, and inherent stories, motifs, myths and rituals. The living crafts (and the ones that are already lost, or the ones that are dying) are practiced over generations, passed on as a legacy, and imbued with familial and societal stories.

"Design creates culture. Culture shapes values. Values determine the future" (Robert L. Peters, President Ico-D, 2001-2003). Similarly, culture also shapes Design.

Design education is a complicated process where inculcating skills of creativity and design knowledge is obviously aimed towards the users/consumers, keeping in mind their needs. However, this process must also be balanced with engendering empathy and respect towards the actual creator/maker and the society in general. The authors believe that this awareness about Culture and traditional crafts, especially in design education, engenders opportunities for growth and revival of our rich cultural heritage and traditions, and this further allows students to explore their milieu and its antecedents, and this fosters creativity. Culture therefore plays an important role to play in education.

The authors believe that in the context of globalization, the understanding of culture, crafts, indigenous knowledge and systems has a very important role to play in design education. The authors aver that awareness of culture is almost a necessity for urban lifestyles. As more and more people are moving away from their hometowns, migrating to urban centres in search of employment opportunities that exist in these cities, they are increasingly coming in contact with people from different backgrounds, both at the workplace and where they live. Awareness and respect for culture, one's own as well as others, leads to fostering tolerance and harmony in a society, and helps that embraces diversity.

"Cultural awareness refers to the developing consciousness of culture and the ways in which culture shapes values and beliefs" (Burchum, 2002, p.7).

The question facing Design educators today is how to align the present generation of millennials with the sensitivity and appreciation of our rich cultural heritage? Thanks to the interconnected world that they inhabit, today's students, although well-informed and more aware, are still living in a protective bubble, inured from the harshness of reality in many cases.

India is a nation with diverse cultures and traditions, and this paper looks at ways and effects of incorporating culture and understanding of crafts and traditions in design education from an Indian perspective. The paper is focused towards the Future of Design Education, and by stressing the need for the knowledge of Culture and Crafts as an integral part of Design Education, the authors feel that this will help the Designers of tomorrow to be prepared for the Future. According to the authors, simply sitting in the classroom or searching online cannot help students learn about Culture and Heritage. To experience culture one has to actually go out into the field, dirty their hands and gather first-hand experiences. This will, in turn lead to a better understanding of the issues and challenges that present themselves to a Designer in the course of their Design journey.

2. Background

"Culture is that complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by man as a member of society." (Tyler, 1870 as cited by Avruch 1998).
The United Nations agency UNESCO defines Culture as the "set of distinctive spiritual, material, intellectual, and emotional features of society or a social group, and that it encompasses, in addition to art and literature, lifestyles, ways of living together, value systems, traditions and beliefs."

Cultural traits and patterns are transmitted from generation to generation and this is an on-going process. At the same time, culture is also dynamic in nature and it evolves and adapts to the stimuli from what is happening around us. According to Burchum (2002), cultural awareness begins with understanding the influences of one's own culture.

It has been amply seen that Culture and Design are interlinked and each complements the other. They are both influenced by and influence each other, mirroring and echoing and also acting as sounding-boards for each other.

Design education, also known as creative education is the teaching of theory and application in the design of products, services and environments, and it involves problem-solving by applying prior knowledge, practical methods and native intelligence to solve the problems.

2.1 Impact of Globalization on Design Education

The modern education system that is prevalent today is primarily influenced by Western ideas, and Post-Industrialization thought process has come to dictate educational process, much to the detriment of indigenous knowledge, traditional lifestyles and cultures. Globalization is the prevailing force today, and it is impossible to not be influenced by it in the march for progress but this suppresses cultural heritage. The authors believe that it is necessary to move with the times, but still keeping the cultural identities in sight through ways and means to adapt to a globalized world-view, tempered with respecting and placing value to the traditional cultures can be a way to achieve this balance. Such measures to make Globalization more inclusive of traditional cultures can lead to a richer experience where the modern coexists in harmony with tradition. Design Education is one important means by which this can be achieved.

Design; like any other facet of the act of creating/producing evolves with times, getting influenced by whatever is happening around us. Advances in technology being an important part of Globalization, have a great impact on Design too. With Globalization generating newer market demands and producers/manufacturers and economies finding ways to cater to these demands, the Design community has also been partly responsible for catering and supporting these burgeoning demands. More and more developing and under-developed nations are trying to emulate the Western ways of life, as these are seen as aspirational, but in this process these nations are abandoning their traditional ways of life that had served them well in the past.

It cannot be denied that cultural and traditional knowledge is a unique response to the local context and have evolved to create a distinct identity for a people. However, this aspirational pursuit of something perceived to be superior (Western ideas) harms what was good in the past in a particular community.

Therefore, these market-driven exigencies ultimately affect Design, and by corollary, Design Education as well. Globalization has meant the rise of a universal mono-culture, and losing sight of the unique identities of traditional ways of life.

A culture based education is defined by Assembly of Alaska Native Educators (1998) as one which reflects, validates and promotes the values, world views and languages that form the culture of a community.

Design is a continuum between the past and the future. Learning from tradition and innovating at the same time, it acts as a connector between creativity and technique, serves to connect creativity, techniques and skills with traditional knowledge.

Culture and craft plays an important role in education and particularly in design education. At all levels of education, essence of culture should be imparted to students' to make them aware about their roots.

2.1 Why it is important for India in the present scenario of globalisation to have knowledge of Culture, Traditions and Crafts incorporated in design Education?

Interweaving culture in design education can be reinforced by engaging students directly with crafts, culture, history, back ground research and analysing so that the students can gain a deep understanding and awareness of their own roots. This further inculcates knowledge of the deep sensitivity and tenuous bonds between a craft and its practitioner, and how the lifestyle of the craftsmen of a particular community is linked to, and directly influenced by the craft itself.

Such interactions with culture and crafts can provide the students with first-hand experiences and further enable them to develop skills and understanding that will help them to explore and experiment with materials, techniques and technologies, and this will lead to creating better self-awareness and critical thought processes.

As cultural heritage has a very important role in forming national identity, therefore the tangible and intangible aspects of this cultural heritage must be preserved and nurtured, and this can be achieved by incorporating the respect and understanding of cultural heritage in Design Education.

According to the International Indigenous Design Charter, designers must make sure that any representation of the indigenous cultures must reflect the cultural values of the community; respects and protects the environment and honors the values enshrined in the traditional lifestyle of indigenous cultures; such works must also be an authentic reflection of indigenous knowledge. In addition to this, and equally important is the need for the designers to ensure that representation must also empower as well as positively impact Indigenous peoples: from the past, in the present, and the future.

As mentioned by Purnima Rai (2016, pp. 27-28), in the present era of technology where everything is mechanized and digitized, India is fortunate that there is an unparalleled resource of hand skills that gives us a distinct edge over any other country in the world.

This rich storehouse provides an opportunity area for young designers to tap into, and create newer synergies. It is the authors' belief that inclusion of Craft education in design curriculums can lead to enhanced creativity, better communication, the spirit of collaboration, problem-solving and resilience, qualities that are expected to be possessed by employees.

During an interview (conducted by authors) on 5 July, 2019, Usha Nehru Patel, a design educationist, Dean IIAD, New Delhi, stated that she strongly feels that being aware of their heritage and culture is very important for the present generation, thus exposure to culture in design courses is essential for the students to develop a clearer understanding of their own milieu and background. Usha also feels that this gives rise to an interesting dichotomy; if one needs to have one's own identity, they need to have something that is different and

original and In the global context this means something that nobody else knows, but only they have an experience of. How a student reacts (embraces or rejects) the cultural aspect would depend on the individual, but it is essential that design institutes provide exposure to traditional crafts and culture to the students. This exposure brings a newer dimension to the whole cultural ethos, with everyone bringing in their original bits, their embodied understanding of their embedded culture to the table. Usha believes that exposure to crafts is important, and it is not only just exposure to craft techniques or a material, but also deeply rooted beliefs and a way of life. Another facet discussed was that while keeping culture intact is not possible since it is not static, but it has to evolve and redefine itself. In this process, some of the old ways would be still embedded in the new.

During a discussion on 5 July, 2019 with Pankaj Narain, a practicing designer and academician mentions that Globalization has had positive and negative effects as well. The good part has been that it has led to a boost in the economy, which has translated into increased opportunities for designers and craftsmen alike but the biggest fear is the dilution or even loss of culture. This is an effect of the current generation getting attracted to things foreign, and ending up losing touch with their own cultures due to availability of too many choices and an overload of distraction. During the interview, it emerged that in his experience, not every student would be interested in crafts and culture, and only a few would genuinely be keen on pursuing more knowledge about crafts and culture. The approach followed by Pankaj means that the craftsman is brought to the classroom as well as students going out in the field to crafts clusters and getting their hands dirty, thus gaining better understanding of these crafts. Thus, empathy is created in the mind of the students toward crafts and culture. Therefore, he feels that in spite of waning interest today, providing a platform to students to explore culture and heritage is still very important.

As the younger generation is rapidly embracing modern technology and increasingly being influenced by globalization, the indigenous and traditional technologies and skills are almost being forgotten and shall soon disappear for want of any patrons. According to the authors, simply sitting in the classroom or searching online cannot help students learn about Culture and Heritage. To experience culture one has to actually go out into the field, dirty their hands and gather first-hand experiences. This will, in turn lead to a better understanding of the issues and challenges that present themselves to a Designer in the course of their Design journey.

According to Darlie Koshy (2017, pp. 1-4) crafts provide differential advantage to design by providing sense & sensitivity. With values, stories and aesthetics all embedded within them, crafts can provide a connection to the heart unlike any other expression. As crafts have both tangible and intangible aspects, they provide a sense of realism and continuity in a globalized world, where a single, standard identity is slowly emerging, with everyone striving to conform to this global identity.

The authors suggest that Design education should aim for the following:

- To create a balanced curriculum that includes the vast repertoire of traditional knowledge that exists with the craftsmen.
- To develop empathy and respect in the minds of the students for culture, crafts and crafts practitioners. This can be achieved by interacting and collaborating with the craftsmen.
- To create design practitioners who can think local and act global at the same time
- To create and shape designers who can think beyond stereotypical expectations of industrial design.

3 Incorporating Cultures and Crafts in design Education (A Case Study)

The curriculum of the Post Graduate Diploma in Interior Design & Styling department in the School of Design, Pearl Academy attempts to address the issues and possible ways forward for students to develop an understanding of the cultural and crafts aspect, and this is done through assignments and design projects that teach self-awareness, empathy, cultural awareness, and ultimately a global view. The projects are hypothetical in nature, and the project brief includes research, case studies, design and documentation.

3.1 Semester One: Familiar to Unfamiliar: Project 1: The Familiar

The cultural and self-awareness aspect is introduced to the students in semester 1 under the Interior Theory Module. As part of this module, 2 projects /assignments are assigned and completed during the course of 10 weeks. Each assignment/project builds upon the learning established in the previous project. Projects also progressively increases in size and complexity.

The first project is very personal, focusing on the individual student's family history-where each student reflects on their family culture, their backgrounds, history, rituals and traditions followed in their family. The teaching and learning strategy in this assignment is based on learning through one's own self experiences and the experiences of their peers. The students are encouraged to discuss on their own experiences of their family culture, and this is designed to encourage cultural awareness.

They talk about their family tree and family backgrounds, their surnames and how surnames generally are markers of community, traditional family occupations, region of origin etc. As a first step, the students gather information from their family members through interviews; discussions etc. and after data collection share their stories with the class in the form of a piece of reflective writing followed by presentation to the class. The students also reflect on the interior design/space planning aspects of their own house. For example: How spaces

were used in their own houses as per their family culture; the concept of purity and impurity in kitchen or in entire house; family shrines and sacred space within the household; the practice of removing shoes outside while entering the house.

The project is important for the student to become aware of the history that has made them who they are, to realize that there is so much similarity yet lot of differences in the way spaces are used in each other's family (for example, most Gujarati families will have a culture of removing shoes outside their house near the entrance). In many cases the students also discover that their family traditions are no longer practiced nowadays due to living in modern houses /dwelling designed keeping in mind global trends. This process of enquiry and exchange of ideas helps students to identify practices unique to a culture/community, and sometimes there are situations where similarities are also seen in diverse cultures.

This sharing of cultural practices and family traditions by the students in a studio setting creates a lively exchange of ideas and thus leads to increased awareness about culture.

3.2 Project 2: Familiar to Unfamiliar

The second project in the module is a group project under the name Design project 1 where the students move to an unfamiliar context i.e. a semi urban scenario/setup. They are asked to do a background research to understand the location/area and then they are taken to the site where each group is assigned one area or scenario and asked to collect data related to background, history ,culture from past to present. The students observe in detail how people are interacting with the space, with each other and understand the culture and context. For research and data collection, various tools are used: interviews, surveys, recordings, sketches etc. After a detailed research for 2 days, students are asked to present a visual scenario of the present culture/trend /pattern. After the second day, the students work in their studios and brainstorm on opportunity areas for design – they have to go back to the background data collected and the scenario to understand the problem /design opportunity in terms of contextual; cultural, social influences. In their final presentation to the class, the students present their design solutions and explain how these solutions will benefit the users, the location and the context and all the stakeholders.

The faculties try to ensure that this particular design project is done in the older parts of the city (Delhi) where some cultural aspects are still alive and where modernity is rubbing shoulders with tradition.

Figure 1 & 2 : Students work as part of Project 2: Familiar to Unfamiliar, Scenario building for Chandani Chowk, Delhi.

Figure 3 & 4: Students in groups presenting Project 2

3.3 Semester Two: Craft Techniques for Interiors

This project is designed with the aim of engendering interaction between design students and craftsmen for design and product development for the contemporary Interiors market. The objectives of this project are: To encourage students to engage with traditional craftsmen; To create areas of shared opportunities for the designers and the craftsmen, within a collaborative process; To foster a two-way learning process along with the spirit of cooperation; To develop a sense of empathy in the students towards the act of creating/making and the maker.

After giving basic input on crafts, meaning of crafts, Indian crafts, the students are explained the importance of crafts in the globalized world, this also includes interaction with designers who are already working in crafts sector. Students are made aware about 'crafting of the spaces'; incorporating crafts- surface making crafts and surface finished crafts in interior spaces. Crafts of all kinds: architectural, functional, decorative are used to enhance and accent these places, which are incorporated on walls, ceiling, floor, furniture, paneling/partitions etc.

The students are asked to choose a craft that they would like to work on, and do a background research on the chosen craft and its context, community practicing the craft, to the present status and then identifying a craftsman with whom they can work with to

develop a product (with application of craft on a contemporary product that can be used in modern interiors)

This module not only helps the students in terms of understanding how design intervention works, but the craftsmen also benefits by getting new ideas for products. As part of an informal survey conducted by the students with their chosen craftsman, it was found that these new products did have acceptance and value in the market. This collaboration develops more confidence in both the students and the craftsmen.

Figure 5: Crochet Lamp (Designer + Craftsmen) *Figure 6: Paper Mache' wall clock by student*

Figure 10, 11: Pattachitra Lamp depicting the Traditional Fish story (Designer + Craftsmen)

Figure 12: Space Divider with Chamba Rumal Craft (Designer + Craftsmen)

Figure 1 to 12 showcase different Interior Products Developed as part of Craft Techniques for Interiors (Designer + Craftsmen) using different craft from India. These products are designed by semester 2 students of PG Interior Design & Styling course at Pearl Academy.

3.4 Semester Three: Hospitality Project: Boutique Hotel

Building on the learnings from the earlier semester, where the students are sensitized towards the understanding of craft and culture in a broader sense:(after incorporating craft in products, another aspect of incorporating craft in 'crafting of spaces' is introduced), In this semester the students work on hospitality space - a boutique hotel, and are given a choice to select one from two typologies, i.e. Contemporary or Heritage. They develop their

understanding about the culture of that region(here culture plays a vital role that dictates the design, and the demographics, climatic response, geographic considerations, local materials, motifs, patterns, colors, styles, crafts etc. all form part of that cultural context).

Figure 13: Mood board for "PadharoMarheDes"- Heritage Boutique Hotel on concept of celebrating different aspect of Jodhpur's, varied culture and exquisite beauty.

Figure 14: View of Bedroom

Figure 15: View of Dining Area for Heritage Boutique Hotel

The student's study how traditional crafts and techniques and indigenous process of construction are used to the best advantage and can also be contemporized without losing their essence. The study of old buildings and their interiors as case study like *Neemrana fort resort*, *Tijara fort resort etc.*, can give us a glimpse of crafts that imbue such habitats with their characteristic regional and cultural flavor, which are missing from modern buildings.

3.5 Semester Four: Final Project

In the last semester of the course, the students work on a project of their choice, and it can be based on any Interiors related topic or space to design. As part of the thesis project, some students tend to choose topics that related to Indian culture and its application in Interiors. It has been seen that exposure to culture in the earlier semesters , does whet the appetites of some students towards the cultural and heritage aspects, and some projects that emerge from this are focused on heritage and culture issues. A few examples:

- The Central Maharani (A Luxury Train that showcase the cultural heritage of Central India).
- Experience Centre for handicrafts of Varanasi, Experience cum Research Centre for Traditional Surface crafts of India at Varanasi for handicrafts of that region.

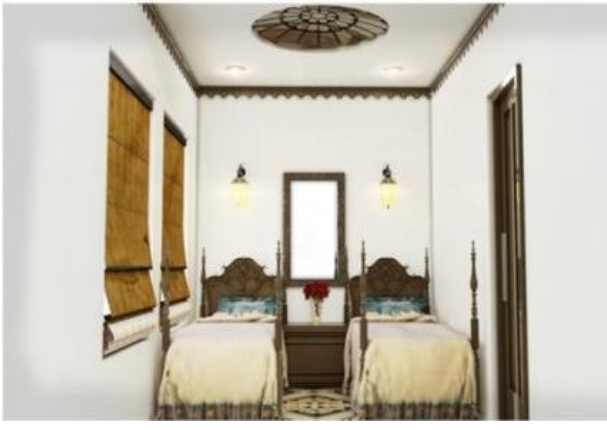

Figure 16: Interior of a Luxury Train depicting crafts , textiles and culture of Madhya Pradesh, India in Interior elements like upholstery, furniture etc.

Figure 17: Experience Centre for Surface Crafts of Varanasi, India showcasing regional crafts & culture

As part of these projects students undergo a detailed research that involves studying the cultural and historical aspects relevant to the topic of their study. In the two year PG course, an attempt has been made to make students connected with an aspect of culture in order to sensitize them towards our rich heritage and cultural background. All these assignments and projects help student to explore ways in which traditional crafts and cultural heritage can be incorporated into our present day built environments, forming an evolutionary response to the changing times, and maintaining our own cultural identity in the face of the onslaught from globalization and not just following a bland aesthetic that eschews all individuality. Students also learn about unfamiliar culture and how culture can be incorporated in a public space. Focus is also placed on application of traditional crafts and local materials in its own traditional essence or contemporized.

4 Conclusions

Design as a formal discipline has emerged after the mid-20thCentury, an era that has been dominated by modernist thought and ideas. Therefore, traditional art and craft have not been considered worthy of inclusion in Design and design research. The Euro-centric models have thus coloured enquiries in design and design education, and relegating a majority of traditional crafts under the umbrella of Ethnic.

However, an increasing call for understanding of issues related to diversity in today's world has also triggered a need for re-examining the Euro-centric ideas and be more inclusive of the indigenous knowledge and skills. According to Alain Findeli (2001, pp. 5-17) twenty first century design must "open up the scope of enquiry". The decline of crafts as seen in today's

scenario has many reasons, few of them is due to globalisation. According to Laila Tyabji (2017, pp. 115 -124) one of the reasons is due to the saturation of ideas, not a saturation of demands, the authors feel that integrating crafts and culture in design education can help in filling this gap.

As seen above in the preceding paragraphs, Design bolstered by tradition oversees the transitions from the past to contemporary values. Therefore, the changes wrought by Globalization are not confrontational with the past; instead, it can be integrated with the past to help perpetuate traditional ideas and sensibilities and prepare them for a new world. Thus, the future can be shaped by the past.

The authors strongly feel that understanding about ones roots, and learning through action must be an integral part of the curriculum for Design education.

The authors believe that Design Education should aim at sensitizing students about the cultural heritage and provide them with avenues and exposure to explore their cultural and contextual backgrounds as they are the future custodians of their culture. Going by current global trends: “Handmade is the new Luxury”, and as we hurtle towards a more technology driven modern world, leaving behind our heritage in oblivion, it becomes imperative to take stock of the value of Heritage and finding ways to keep the traditional knowledge alive. And as mentioned by Purnima Rai (2016, pp. 27-28) in one of her papers that In an increasingly mechanized and digitized world, our unique good fortune in being able to access an unparalleled resource of hand skills gives us a distinct edge over any other country in the world.

> “Whoever wishes to foresee the future must consult the past; for human events ever resemble those of preceding times. This arises from the fact that they are produced by men who ever have been, and ever will be, animated by the same passions, and thus they necessarily have the same result.” (Niccolo Machiavelli, 2017, p.222).

Abstract | Codesign includes end-users in the design process. Ideally codesign occurs at many points in the design process however, in an education setting often only one codesign workshop is arranged. This study investigates teaching design students the value of codesign through a long-term funded project aiming to reinvent the future of the cinema for millennials. We involved non-designers, in codesign activities with mixed disciplined design students. The projects favoured by the end-users intertwined the ritual of going to the cinema, with the culture of sharing experiences with friends, with modern digital services. We argue a minimum of two codesign workshops are needed to generate valid ideas and maintain an ongoing voice of end-users in the process. Codesign materials needed to be carefully chosen for end-users to articulate their ideas and for design students to trial this new language, translating end-user views into innovative designs for the cinema sector.

KEYWORDS | CODESIGN, USER-CENTRED DESIGN, DESIGN METHOD(S), DESIGN EDUCATION, PARTICIPATORY DESIGN

1. Introduction

Design has been characterised as an intuitive, inward-looking process that ends when designers arrive at an aesthetically pleasing concept, they consider fits the client's brief. Traditionally, in design practice, clients provide the content and designers create the form. The view that designers owe their allegiance to clients rather than end-users is still prominent in practice however, with the rise of participatory and user-centred design approaches, designers want to know how to engage with end-users and what the benefits are. Codesign includes end-users as design partners in the process with the aim of harnessing their contextual knowledge and creative ideas. Ideally codesign occurs at many points in the design process however, in an education setting often only one codesign workshop is arranged, making it easy for designers to ignore or misunderstand end-user voices, extracting ideas using intuitive idea generation processes. The main challenge is choosing codesign materials suitable to give end-users a strong voice and enable idea generation that informs innovative design at several points along the design pathway.

This study specifically looks into teaching the next generation of design students the value of a codesign process on a long-term funded project aiming to reinvent the cinema of the future for millennials. The authors of this paper led and taught and the codesign process to mixed disciplined Master of Design students, at Swinburne University of Technology inviting non-designer end-users into our classes. Each year, for four years we arranged two codesign workshops to understand the current cinema context and why cinema attendance is declining in Australia, following a global trend. The design students and non-designers then co-created future cinema scenarios suiting millennials' preferences. The codesign processes included games, card sorting, think aloud, probes, and superhero toolkits. A thematic analysis of the barriers to cinema attendance across the four years showed that millennials regularly choose to watch movies at home alone or in social settings with food. They reported barriers such as getting dressed up, finding a friend who liked the same movie choice, the high price of cinema and travel to the cinema, and surprisingly leaving pets at home after a day at work or study. The codesigned project solutions presented in this paper centre on reviving cinema attendance through, personalised collectable tickets, making memories with friends, enhancing the cinema atmosphere by digitally lighting the corridors and combining going to the movies with treasure hunt gaming experiences.

2. Understanding codesign and the cinema experience

2.1 The stages of codesign

Codesign is growing as a design method, however debate continues about when and how many times to include end-users in codesign workshops. A design project typically involves three stages, each presenting an opportunity to include end-users, the exploratory,

generative and evaluative design stages (Hanington, 2007). In codesign, the exploratory stage aims to understand the project goals and context and reviews past design concepts; in the generative stage designers and end-users redefine goals and co-create a range of design options and prototypes, in the evaluative stage, designers and end-users iteratively shape the designed concepts into final design prototypes continually checking they suit end-user needs (Spinuzzi, 2005).

Most of the research literature agrees, incorporating end-user ideas early in the design process is vital to ensure project goals are sound (Hanington 2007; Lofthouse & Lilley, 2006). Research shows that eighty percent of decisions are made in the first twenty percent of project time, showing the importance of planning a codesign workshop early in the project duration (Kleinsmann et al., 2007). Some argue typically the largest proportion of codesign activity happens in the early phases of design, called the "fuzzy front end" (Sanders & Stappers, 2008). Planning a second codesign workshop in the generative stages of design is shown to help to reduce the number of unworkable ideas (Hoonhout, 2007).

Authors claim codesign workshops should occur at many points in a project duration, in the pre-design, generative, evaluative and post-design stages (Sanders & Stappers, 2014). If designers can develop an ongoing relationship with end-users then all stakeholders become invested in the project (Honnhout 2007; Visser et al*.,* 2005). Working with end-users has been described as "a cascading process" suggesting better designs will result from a continual cycle of end-user research (Reich et al., 1996). By listening to end-users' views, drawing on end-users' expertise and understanding end-users' goals at all stages of the design process researchers advocate the end product will more likely suit end-users' needs and preferences.

Generative toolkits in the context of codesign workshops are a means to uncover the needs and preferences of end-users, allowing hidden project issues to surface (Sanders & Stappers, 2014). Generative toolkits are design-led activities where designers create the toolkit to suit a project context and support end-users to give creative input. Previous authors have designed maps of when generative toolkits should be employed across the various stages of codesign workshops (Sanders & Stappers, 2014).

Teaching design students end-user research methods has in the past revolved around techniques such as focus group, observation, questionnaire and interview, where end-users are observed for insights and information is extracted for a designer's brief. This review shows that understanding how and when to invite end-users into the classroom to participate in codesign workshops with generative toolkits with real world clients is little known. The study presented in this paper began with the broad aim to understand how codesign processes benefit design student learning.

2.2 Challenges of cinema design: Why do people go to the cinema?

Cinemas are sites of cultural significance and there is a renewed interest in studying the

social and spatial dimension of cinema attendance (Bowles, 2011). This is relevant as the design of the theatre spaces reflects social practices such as "getting together with strangers in a darkened public venue" (Bowles, 2011, p. 854). The architecture of the theatre has been designed so that patrons may forget the outside world and become immersed in an environment free of reminders of 'reality'. The notion of escaping reality is common in cinema marketing strategies. The design of the lobby, screen, lighting, room proportions, sightlines and seating are used to create this phenomenon (Muffoletto, 2011).

Part of the positive experience of going to the cinema is explained by its quality to escape from everyday life (Addis & Holbrook, 2010; Katz et al., 1973). According to Muffoletto: "People go to the movies to be emotionally immersed in an environment that excludes reminders of their daily routine" (2011, p.1). In times of stress, such as war, movie theatres sell escapism, contributing to their success and longevity (Jeacle, 2009; Ratner, 2003). However, Muffoletto (2011) proposes that the escapist quality of the movie theatres has declined due to increased contact with the outside world whilst being in the theatre. He suggests the use of smartphones to text, social media and access to movie reviews or trailers, is responsible. He also suggests that for the younger generation "letting it be known what they are doing" has become a part of the shared social experience as much as the film viewing itself. According to Lee and Ma (2012) the value of any form of media entertainment lies in an ability to satisfy users' needs of which one can be escapism.

The cinema industry has a history of success due to its longevity, its financial success and cultural significance. Despite millennials spending more time watching movies at home via evolving technology, the time spent watching movies in a movie theatre has remained consistent since 1970 (Sedgwick, 2004). Traditionally, cultural theory and the importance of the film script itself have been areas of research in the film industry (Sedgwick, 2004). Research has been conducted into film form and content over other factors (Bowles, 2011), however there is a gap for designers to reinvent the cinema as a space, service and desired experience.

Research supports the theory that consumers use media such as film, online gaming and social media as a form of escapism. There is evidence that providing patrons a sense of escapism through the movie theatre experience is a key element of cinemas' ongoing success. While some research into how the design of the physical space of a theatre creates a sense of escapism exists, service design, and the overall cinema experience (including before and after the film) are neglected topics. With progressing technological advancements, the underlying traditional desires of escaping and new trends of sharing the experience should be catered for in innovative ways. This is what this codesign project aims for.

3. Method

This study sought to understand how codesign processes benefit design student learning in regards to the future cinema experience. The spirit of entering into the codesign process was positioned according to Cross (2004), that anyone can be taught designerly ways of knowing. Each year, over a four-year period, two codesign workshops were arranged during a twelve-week semester, involving an iterative process of exploring, designing and reviewing ideas. First the designers undertook a literature review, then they conducted site visits to the cinema to understand the design context. After this, a variety of generative toolkits were trialled in the codesign workshops for a large cinema retailer in Australia. The workshops were each two hours long and held in large open space rooms in the university.

The designer participants were from the Bachelor of Design and Master of Design programs in an Australian university, ranging in ages from 22 to 40 years. They were all from different design discipline backgrounds including architecture, interior design, communication design, digital design, product design and fine art, most with previous design industry experience. The non-design participants were family and friends of the designers, other university students and staff, representing lead end-users of the millennial age group. By inviting non-designers into a series of codesign workshops, the designers were challenged to create generative toolkits to build ideas together with non-designers, which they had never experienced before. Here, the study built on Sander's call for designers to create spaces that she terms "scaffolds" where everyday people express their creativity (2002).

Experienced university lecturers art directed the design work each year and this paper's authors supported the design students to facilitate the codesign workshops themselves. Other student designers took notes of their general observations of the codesign workshops, participant survey question answers and they wrote their own reflections immediately after each workshop. The informal nature of notetaking was important to allow transparency and continuous checking to occur (Lincoln & Guba, 1985). This paper's authors photographed the workshop process and the design outcomes.

The data sources used in this case study included existing marketing material provided by the client, site visits, workshop photographs, design prototypes and ideas used before during and after the workshops, design outcomes, observer notes and survey reflections. For analysis, all the data sources were organised chronologically under activity headings into a large case report. The analysis was organised in colour coded themes answering the broad question: "What are the lessons learnt from trialling codesign workshops in design education?" Following are the findings, outlining what students discovered from trialling two codesign workshops and the overall lessons learnt.

4. A case study: Codesigning the future of cinema

The client had undertaken previous market research to understand the barriers to cinema

attendance and the strategies to attract millennials out of their homes, bars, restaurants and into the cinema. The authors of this paper focused on two issues: teaching the students codesign skills and codesigning novel solutions to attract millennials back to the cinema.

Before embarking on the first codesign workshop the majority of students admitted they had not heard of codesign as a design method. There was confusion about who they would be working with. Some said they thought codesign would be about engaging with clients, others said they imagined engaging with different designers or people with different backgrounds. Others said they were excited to learn a new method that they could use in their jobs. One student commented: "I didn't know too much about it, however I knew it would be a good skill to develop as a designer." Several students were nervous for example one student said: "I'm unsure about codesign, it sounds messy and scary because you have to deal with strangers." However, on the whole, comments were positive such as: "It sounds like a really interesting area that I would like to be more involved in and learn more about."

4.1 Co-design workshop one

Students were encouraged to create activities with inspiring materials that would help them find out about moviegoers needs and preferences and the barriers to cinema attendance. The codesign activities ranged from model making with beach, forest and outer space themes, Lego play, creating mood boards, journey maps and card games aiming to find out what end-users would like as an ideal cinema-going experience and about their nostalgic memories of past experiences. One student's activity was to create a future mood board about the experience of waiting for the movie to start. This student used a pop-up stage moodboard where non-designers pegged images onto the string (Figure 1). Another student used superheroes in the corridors to prompt discussion about how the corridors could be lit up after an initial finding that they were dark and depressing. One student was to create a personal cinematic profile card. Another activity was to map positive and negative experiences in the cinema on a mood board. One student asked the user to imagine themselves as a superhero either in the café, foyer, or entrance of the cinema (Figure 1). He wanted to find out what characters they liked. One activity asked participants to view images of a specific movie, and then pick out given words to describe what they were feeling. Finally, one student created a 'cinema experience' journey map. She provided printouts of different items (popcorn, wallet, tickets and emotion icons) to facilitate a creative conversation.

When analysing the success of the codesign toolkits, the authors discovered that games were the most engaging form of toolkit activity. Games provided the opportunity for participants to chat about their ideas while playing. The students were delighted with how much conversation they had with the participants while playing games, gaining great insights, information and opinions from the participants. Students were pleased that their codesign toolkits prompted many ideas: "It was really engaging and a lot of brainstorming was done"; "It was quite engaging and straight to the point"; "The users liked it and we got a lot of suggestions"; "People were very interested to participate in the activity because they said it

was very creative." The toolkits acted as prompts for quick engagement as one student said: "Because my fortune wheel was very attractive, it was a good excuse to get them engaged." Another said: "I not only gathered the information I needed but I also found other concerns and possible solutions related to the cinema experience".

Figure 1. Top row shows the trivia hunt toolkit investigating options for the game. Bottom row shows three toolkits: a cinema mood board on a stage with pegs; a superhero dress-up game, and a build your ideal cinema with Lego activity.

After the first codesign workshop, we discussed ways of improving the students' codesign toolkits in preparation for the second workshop. Students commented in the future they would make their toolkit more fun and more flexible. Students realised, if a non-designer participant wasn't comfortable sketching, then their toolkit was wasted on them. Overall, the students concluded that most of their toolkits in the first workshop were far too complicated while others needed to be more varied to prompt conversations without requiring a lot of explanation. The students reflected that group toolkits save time where more people can listen and record ideas on the spot. One student said: "It was hard to capture ideas quickly – have two people, one can scribe". Students realised the benefit of having attractively designed toolkits to create interest. At the same time, they realised a lot of money didn't need to be spent to make the activity still worthwhile which was a relief for international students without a lot of access to resources. Some realised activities can be too open ended, where it would be better to ask more specific questions. Many decided for the second workshop a game would be the best to allow for fun interaction. One student reflected: "The activity was so fast, so I think I can make it a little longer and deeper to explore more information".

The students all agreed in the second workshop, it would be better to include more visual materials such as images, cartoons (for example movies scenes and characters) and have less text, words, rules and descriptions as part of the activity. One student said: “Next time I need a toolkit where people don’t have to write a lot”. The students realised in the future they would sit back and allow the end-users to take over creating artefacts and models themselves. One student admitted he was not very good at facilitating but learnt a lot by listening to the discussion of the group. Another student said it would be better to: “personalise the experience more, for example having a photo that shows you as the principal character”. This student went on to design a personalised collectable cinema ticket with a photo of the person buying the ticket embedded on a printed ticket. Many of the participants said collectable tickets would be something they would put on the fridge or share with friends or hold onto as a keepsake (Figure 2).

Figure 2. A student design proposal showing how cinemas could use a photobooth or an app to create personalised, collectable tickets.

4.2 Co-design workshop two

The aim of the second workshop was to trial refined codesign toolkits to further understand the barriers and preferences of cinema-going millennials. The students were challenged to propose a design solution to refine with non-designer participants. The second codesign

workshop was an important chance to gather end-user insights to help shape their design outcomes for enhancing the youth's movie-going experience. One student thought the entry hall was the key area to focus on, as he discovered that participants thought the corridors were dark and depressing which was an opportunity to redesign. He codesigned a corridor with projectors installed to light up the corridors with images of the next blockbuster movie and lights to lead people into the cinema where the next movie would be shown (Figure 3).

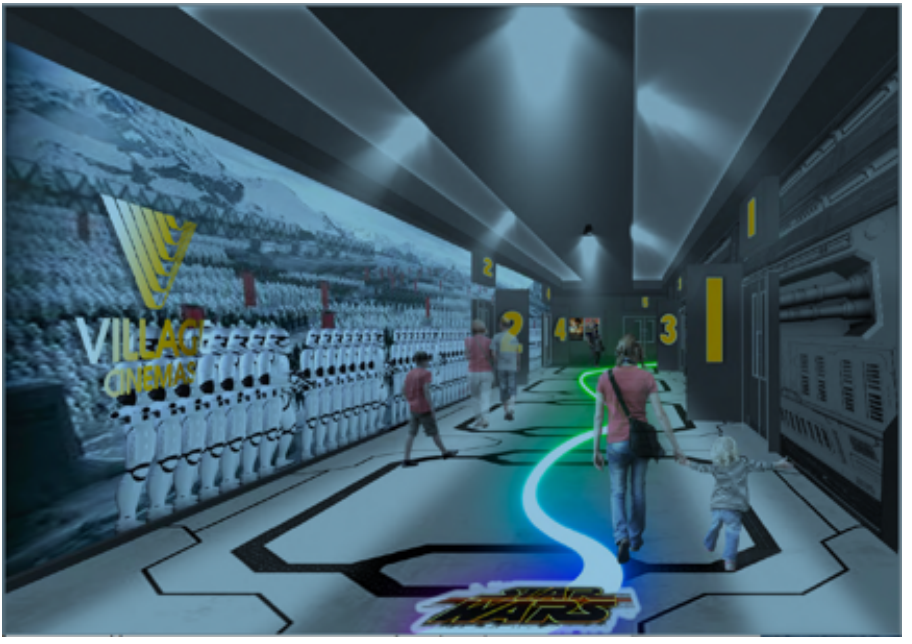

Figure 3. A student design proposal showing how the cinema corridors could light up with projections of movie images and show the path to the cinema door.

One student said: "Users are more creative than I thought". She discovered, that: "People like the idea of a game that makes you walk around the cinema". It was one of the end-users who came up with the idea of augmented reality for a treasure hunt game she called a "Trivia Hunt", showing how the codesign activity directly influenced her design concept. She explored a scavenger hunt idea, combined with trivia creating the Trivia Hunt concept (Figure 4). The idea was that trivia questions based on a film represented in a poster would be hidden in locations around the cinema for patrons to search for. Once patrons find the answer to the question, they enter it into their phone linked to a QR code for the chance of winning a prize, such as a movie ticket or a free popcorn.

Figure 4. A student design proposal showing a poster advertising the Trivia Hunt concept linking to an app with the clues to follow.

The designers' rule "form follows function' was stressed by a non-designer when one student said: "I found that cinema goers valued function above all… for example expense was an issue". Millennials repeatedly discussed the price of the movie as a major barrier to attending the movies. The social aspects of going to the cinema was also repeatedly discussed. Debriefing and chatting with friends after the movies, was something that all participants wanted a design solution to cater for. One student found: "The obstacle of deciding on when to go [to the cinema], with who and what to see is much bigger than I anticipated". In response to this, the student recommended the cinema team up with a dating app to find a friend to invite on a first date to watch a film together. Another student found: "People really want to bring their home to the movie theatre." So the interior design students got working on comfortable seating like couches with rugs and cushions. Others worked on solutions where a dog salon would see their pets being pampered in the foyer while they relaxed watching a movie as leaving pets at home after a day at work was another barrier to going to the movies.

4.3 Lessons learnt

At the end of the semester after conducting two codesign workshops, the authors of this paper asked the students about their experiences. The students used the words 'fun' and 'engaging' to describe their experiences with codesign toolkits and real-world participants. One said: "it was fun, I gained practical and new perspectives" another said: "I got lots more insight than I imagined." Another said: "People talked more after fun activities, and they felt more comfortable in this kind of atmosphere." Several students acknowledged the importance for final design outcomes to include end-users' perspectives. For example: "It's a

very unique way to shape your design development with solid information from the real users" and "it is a very good tool to design not only products but experiences as it is important to know the thoughts and opinions of end user." One student acknowledged that in the end the designer needs to make a decision to move the design forward, stating: "It can be very fun and creative … designers still need to make a call". In order to get feedback whether the final design proposals were suitable from a business perspective, the client was invited to the final student presentations to give feedback on the fit of the ideas for their business. The feedback was overwhelmingly positive – in particular on the ideas presented.

5. Conclusion

We found codesign to be a useful method when applied twice in a twelve-week university semester: the first workshops uncovered barriers to cinema attendance and the second suggested suitable prototype ideas. Two codesign workshops are sufficient to give designers a taste of working with rich data, where final designs are not based on intuitive assumptions. We found a codesign process trialling toolkits became a language facilitating ideas between different disciplines and stakeholders. We suggest a new important role for designers is to find their voice in orchestrating this language. We argue a minimum of two codesign workshops are needed in design education to generate validate student ideas and keep an ongoing voice of end-users in the process. The codesign materials need to be carefully chosen for end-users to articulate their ideas and for design students to trial this new language, translating end-user views into appropriate designs. The projects favoured by the end-users intertwine the ritual of going to the cinema, with the culture of sharing experiences with friends, with modern digital services. Revisiting past social connection behaviours such as going to the cinema can benefit future generations. This study reveals the potential of codesigning a cinema attendance strategy, moving beyond pure entertainment into concepts that contribute to improving society's isolation and loneliness concerns. We suggest that codesign processes rather than traditional designer-client processes, offer novel solutions for clients looking to come up with innovative concepts for enhancing their existing business models.

Abstract | This paper explores the culture of letterpress printing within Art and Design education in the UK and Ireland. It describes two phases of research over the last four years. The first is based on an immersive collaborative letterpress research project, in which staff and students from six UK Colleges worked together to research, write and print a letterpress publication. The second phase is a comprehensive, systematic field survey of all of the remaining letterpress workshops within Art and Design Higher and Further Education in Britain and Ireland since 1955. The combined findings of these two phases of research enable the authors to form a position in relation to the changing culture of letterpress and its role in education.

KEYWORDS | LETTERPRESS, TYPOGRAPHY, PRINT HISTORY, DESIGN HISTORY, PRINTING

1. Introduction

This chapter outlines the current breadth and depth of letterpress practice within contemporary art and design pedagogy across the UK and Ireland. It is based on the field research data which has been systematically gathered through visiting the letterpress workshops in Further and Higher Education. These research survey visits to Art and Design Schools involved traveling over 8,400 miles between 2014—2019.

Throughout the major part of the twentieth century, the teaching of letterpress was organised through training centres in technical colleges and art and design schools. This 'training' as opposed to 'educational' model is now long redundant, largely due to the growth of digital technologies the 1980s and developments in design Education. Letterpress printing, however, is more popular than at any time in since the 1990's. The current resurgence of interest in the letterpress process makes this research timely as it examines how the education of artists and designers has changed and developed since the 1960s.

The collaboration between the principal researchers began 2011. It has involved two interconnected research projects. The first part linked six colleges with active letterpress workshops from around the UK. Staff and students from each college united in a collaborative project that allowed them to consider both the practical and philosophical approach to letterpress practice. Entitled *6x6: Collaborative Letterpress Project,* it provided an insight into the different approaches to letterpress within the six colleges.[1]

The second part grew out of this first collaboration in 2014. The research team asked the question, how widespread is the use of letterpress in art and design education today, as compared to its mid-century heyday?

The research has identified 43 Art and Design institutions which have active letterpress workshops. We have visited and surveyed 41 workshops, the research has systematically identifying and cataloguing the equipment and presses, type sizes and faces, both wood and metal. We have undertaken a measured survey of each workshops which supported the development of orthographic drawings to a common scale providing a physical representation of each space.

[1] The collaboration was between the *University of Brighton*, *Camberwell College of the Arts* (UAL), *London College of Communication* (UAL), *Central Saint Martins College of Art and Design* (UAL), *Lincoln School of Art* and *Glasgow School of Art*. Each had an established history of using the letterpress, and with the exception of Lincoln, had workshops staffed by a dedicated technician. The staff and students involved were all from Graphic Design or Visual Communication programmes.

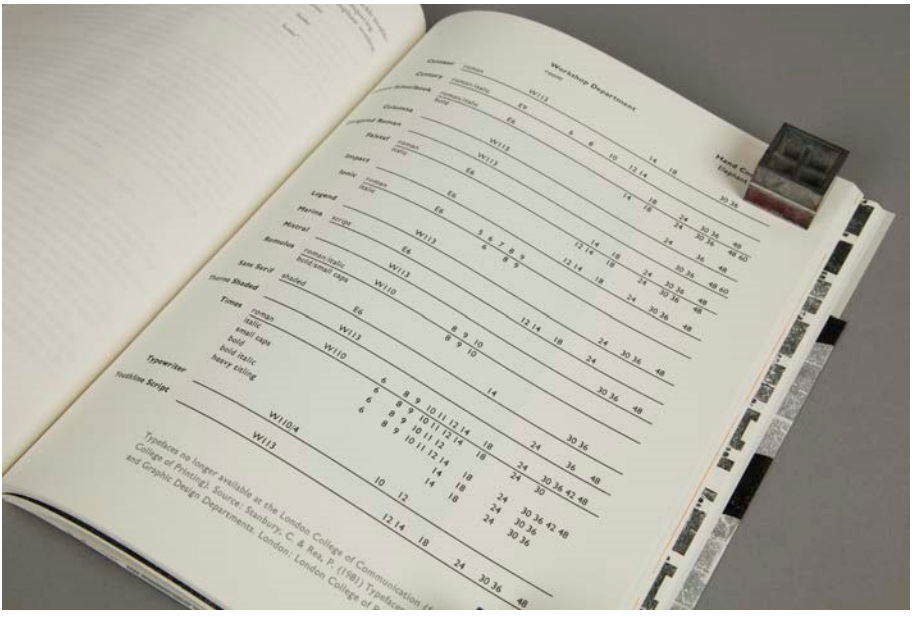

Figure 1. Student work from 6x6: Collaborative Letterpress Project, 2014.

2. Identifying a timeframe and the extent of the field of research

In order to trace how letterpress workshops and teaching have changed within Further and Higher Education it was important to establish a clear datum point from which to start. Two key sources from the *Charles Pickering Archive* LCC provided this datum point within an appropriate time frame. The typed and hand-annotated list entitled *List of Establishments for Further Education Where Courses or Classes in Printing are held 1955* is believed to have been compiled by Beatrice Warde and the *Guides to Educational Courses in the Printing Industry 1967.* The 1955 list has 72 colleges and 1967 44 colleges (44 colleges appear on both lists) and provides a list of courses leading to qualifications that could be studied relating to training for the print trade. The two principal sources were combined together with the eight additional institutions, and organised into a single list alphabetically by city or town. The total number of letterpress workshops within educational art and design FE and HE schools and colleges responsible for the training of designers and printers was established as 104 in 1967.

Tracing the history of institutions on the combined list reflect the major changes in art and design education in the UK during the twentieth century. The first significant change was the

move from the *National Diploma in Design* (NDD, 1946–1961). In 1960, the *Coldstream Report* outlined decisions to develop a *Diploma in Design* (Dip AD, 1962 – 1974) (H.M.S.O. 1960), with only sixteen colleges awarded it in the first round. It is this legacy that is evidenced in the absence of many of the original colleges listed, for '*Coldstream had promised institutional autonomy but his committee's reforms led to increased centralisation and the closure of almost two hundred art schools across Britain'* (Llewellyn, 2015). This was a significant watershed as Technical Colleges and Art and Design Schools either retained pre-degree courses, in Further Education, or developed degrees within Higher Education. The next substantial change came in 1992, when Polytechnics were granted degree awarding powers. This has been referred to as *'The polytechnic era'* (Llewellyn,2015), the period 1965—1992 that was dominated by the *Council for National Academic Awards* (CNAA, from 1974 –1992). The last major educational change was the shift from a student grant to student fees and the adoption of student loans first introduced in 1998, followed in 2009, by a rise in student fees to £9000. The dates 1967–2020, provide bookends for our research.

2.1 Research Methodology: The Field Survey

The field survey set out to answer four interrelated research questions:

1. How many active letterpress workshops are operating within British and Irish Higher and Further Education?
2. Where are they located and within which Institutions?
3. What do they contain and how are they arranged?
4. How are they being used?

Having established the number of institutions which could have active letterpress workshops we began to systematically contact each by phone and then email. We established that 43 Institutions from 104 had retained letterpress equipment. The field research was supported by small funding streams from a range of sources.

2.3 Plotting the Scale of the Survey

Using an OS map~~s~~ of the UK and Ireland we began to plot the position of the 104 workshops using a single yellow dot for the 1955 list, single orange dot for the 1967 list and an orange roundel with a yellow bull for those institutions identified as entries on both lists. We now had a distribution pattern that revealed the post-war period had a significant number of small institutions located across the UK (Beck and Cornford, 2012). The distribution pattern linked, as might be expected, to major cities towns or urban conurbations. We developed a second map plotting the 43 institutions which had confirmed letterpress workshops. These colleges can be broken down geographically: Scotland (4), The North England (10), The

Midlands (5,) Wales (1), Republic of Ireland (2), South East England (15), South West England (7).

2.4 Ensuring Consistent Data Gathering

To ensure consistency and comparable results it was important to develop a transferable methodology for collecting the data. Letterpress type is stored in cases within cabinets which characteristically have space for 22 cases. We designed a simple form with 22 lines, and columns for: font, weight, size points/didots, foundry/manufacture to catalogue wood and metal type. A comments section at the bottom was used to record the cabinet maker, where this could be identified. As all the workshops contained several cabinets each form was numbered. This systematic process has provided a record of every cabinet and every case, workshop by workshop. A second form was designed to record the equipment.

2.5 Surveying Physical Workshop Spaces

As well as the type and equipment we wanted to survey the physical space. We made the 1:50 digital scale drawings. The scale drawings enabled us to compare workshops: size, organisation, workflow and student capacity. A combination of the survey and conversations with technical and academic staff, revealed how many students could be taught in ~~t~~each workshop. This is a critical feature of modern HE education where institution wide staff student ratios (SSR) are often applied to funding models which can restrict small group workshop teaching or make it prohibitively expensive.

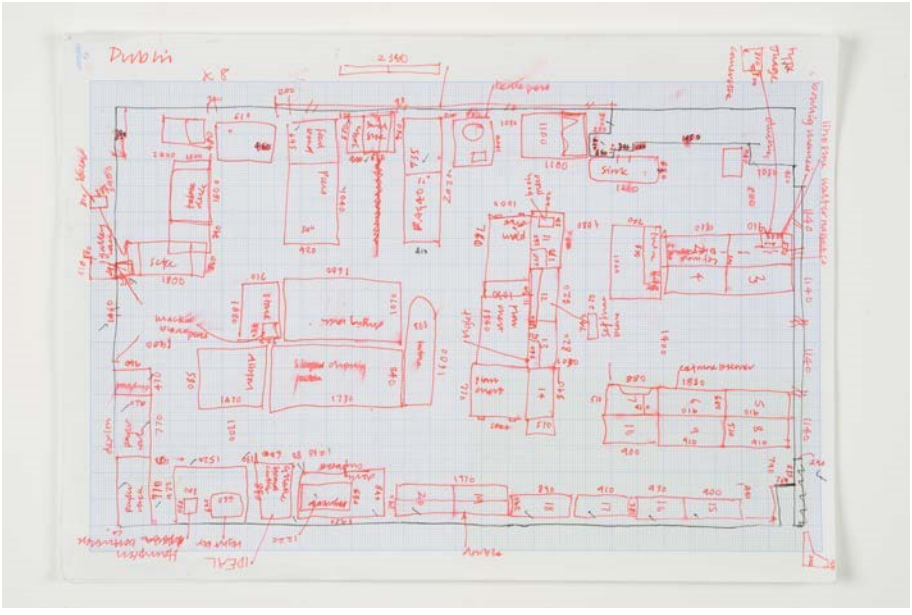

Figure 2. A sketch of the workshop at National College of Art and Design, Dublin. This information was gathered onsite and worked up into a digital map afterwards.

3. Workshop Initial Findings: Type

We have completed surveys of 41 of the 43 institutions (44 workshops), a further three surveys have yet to be undertaken. The 41 workshops surveyed to date contain a total of 490 cabinets or type frames, which hold 9,272 cases of type. This figure can be further broken down into lead type, 8,132 cases, wood type 1,140, cases and 22 cases of Acrylic type. Today there are no institutions working with 'hot metal composition'. No college has the capacity to cast their own type. The restrictions of contemporary Health and Safety practices identify the risks involved of working with molten lead. The *Monotype* casters from the *London College of Communication* (formerly *London College of Printing*) were donated to the Type Archive (London) in 2003. As a consequence of this loss, the quality of the type catalogued varied tremendously across different workshops. Some had seen heavy usage, some remained pristine in cases – particularly smaller, composition sizes that are labour-intensive to typeset and print.

Collections of wood type are vulnerable to theft as the attraction of acquiring a large wooden initial has appealed to generations of design students and as a result we found many cases of wood type labelled 'mixed', where incomplete cases had been combined. Modern digital technology has enabled laser cutting, 3D printing and CNC routing. In several

workshops we saw student and staff designed fonts and type blocks cut on end-grain wood as per historical manufacture and single designs mounted on type-high MDF in the manner of relief block printing, letterpress is not now exclusively defined by the use of moveable type.

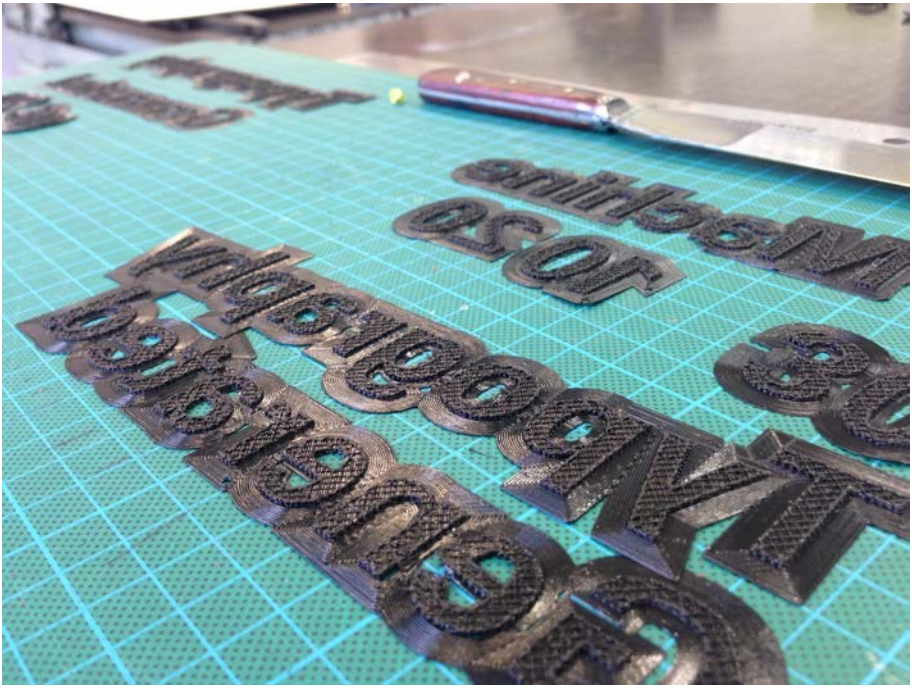

Figure 3. 3D printed type, in the process of being mounted to type height to print.

3.1 Workshop Initial Findings: Presses

The workshop survey only records the position on the measured drawings of presses which were used for letterpress printing. It does not record all the relief printing presses in each institution in a printmaking workshops which may be used for, lithography, etching or mezzotints *etc*, nor those unused presses displayed in entrance lobbies as artefacts. The range of equipment, and particularly presses, varied across the different workshops. The 41 workshops surveyed to date contain a total of 84 large presses located in fixed positions within the workshops.

Today each workshop contained galley and/or proofing presses, there advantage is that students can use them under supervision. As each pull relies on hand feeding the press it is

only possible to produce small volumes This has democratically opened up the possibilities of print production, students have authorship over each stage of the process of their work and are physically responsible for its execution. The student is in a position to produce multiple editions. By contrast, digital printing is often used by students to prototype, or produce a one off for a critique or review. Letterpress is not a facsimile of print, it is the actual print. It offers the student opportunity of working with: metallic inks, florescent colours, pastels and printing white over a colour. Students can emboss, deboss and foil block. Educationally, this promotes a freedom and a range of print that is not possible within digital production.

3.2 Workshop Initial Findings: Layouts and Patterns of Use

At each workshop visited, the space survey and the making of measured drawings provided an insight into how the workshops are used for teaching and experimentation. The set-up had significant influence over the teaching and use. There are workshops in which the type is stored separately from the presses which enable students to set type when technical or academic staff are not supervising but do not support independent printing. We identified workshops in which all the equipment the paper, type, presses and drying racks are contained within a lockable space supported by a dedicated letterpress technician in which students can compose, proof, print and diss type under supervision. There are workshops in which the letterpress equipment is contained within a larger general printmaking room which may also support, mono printing, etching, mezzotints, lithography, and screen-printing *etc* and is supported by several technical staff with a range of printmaking expertise. There were also studio spaces containing type cabinets and a hand proofing press, characteristically a *Farley*, which enables students to compose and print independently. Only two dedicated workshops that had escaped closure were largely unused and without technical staff.

Figure 4. The workshop at Birmingham City University, with type cabinets and a Farley proofing press.

4. Reinstating Letterpress

Many of the staff with responsibility for the workshops are more investment and influence on the type collections within the workshops. At *Arts University Bournemouth* Sally Hope Course Leader Visual Communication has built up a collection of wood and metal type, acquired cabinets and cases, a stone and a *Farley Press* through which she introduces students to the process. Designers and academics Barry Tullett and Philippa Wood at the *University of Lincoln* house *The Caseroom Press* within the undergraduate Graphic Design Department. Their collection of predominantly wood type and typewriters is closely connected to their practice led research (Tullett, 2014) and this, in turn, informs their teaching. Students across all three years are taught the process through workshops which respond to Tullett and Wood's own experiences as students.

The latest Letterpress workshop to be reinstated is at Kingston School of Art (KSA), *Kingston University London*, the *'**noble**press'* was founded in May 2017. *Kingston Polytechnic* had a letterpress workshop until 1992 (the same year it gained University status) when with the

retirement of the technician and an investment in new Macintosh Computers the workshop was dismantled and the presses sold.. The set-up costs of £67,000 to establish the workshop must be considered in relation to the durability and longevity of the equipment. If serviced regularly the presses could be rolling for well over 100 years, as is demonstrated by Camberwell's workshop which is the oldest in the same location since 1906. Letterpress equipment is rising in cost and so the presses and type are increasingly valuable assets.

5. Workshops and Curriculum Developments

The use of the letterpress process within each workshop varies according to the history and culture of the institution. The technical teaching of letterpress composition was phased out at all colleges by the late 1980's. Digital composition rendered print apprenticeships irrelevant. The impact, scale and speed of change on the print industry and its knock-on effect on technical education which supported it in the was colossal through the mid 1980's. Little more than a decade earlier, the print industry of 1970 employed 300,000 people in the UK. As late as 1985, 266 printers traded in the City of London, one of London's major print areas, 111 of these were letterpress workshops.

Today, the workshops are used by a broader community of art and design students. Groups of Graphic Design, Visual Communication and Illustrators and printmakers use the space. When open access policies are adopted photographers, fashion students, architects and product students are often working alongside each other. The mode of teaching delivery varies from institution to institution, but the majority of colleges have an induction process to the workshop area, which is delivered by technical staff. This enables students to work independently with access to specialist support and technical guidance. Students at the majority of colleges are encouraged to explore design briefs through a range of media which may include: interaction, film, publication, print and print processes including letterpress. Some, including *Cambridge, Glasgow*, *Kingston* and *Lincoln*, stipulate a letterpress outcome on workshop or project briefs and therefore ensure that all students gain an induction into the area. Others have attempted to further embed it within curriculum through assessment submission requirements. In a strategic move to protect the workshops, courses have explicitly mentioned the letterpress process within validation documents, ensuring the preservation of the workshop. This was achieved when the workshop at *London College of Communication* was under threat in the early 2000s after several years without a dedicated technician. Both of these approaches mean that each student on the course in question can gain experience of the process, and work on the assumption that the most engaged students will return to undertake longer projects throughout the duration of their course. The wider adoption of letterpress as a medium by students is therefore primarily through self-selection.

Following the survey visits we conducted a series of telephone interviews with the staff responsible for the workshops which provided an insight into the way they are used in relation to curriculum. Edwin Pickston at *Glasgow School of Art* (GSA) identifies the advantages of the *'Caseroom'* to *Visual Communication* students. For Pickstone the workshop presents the history of type. This is important as, *'The principals of metal type underpin the systems which controls what's going on digitally today.'* Letterpress provides the todays Graphic Design students with a direct link to the process of reproduction key to the historical dissemination of knowledge through the printed book. For students who are familiar with digital type through word processing the origins of, typeface, size, columns, alignment, kerning (horizontal spacing), leading (vertical spacing) and alignment are made real through metal. The letterforms of type can be traced back to calligraphy, notation and writing systems leading to the origins of the alphabet. The link with history was a common thread with staff responsible for workshops. Pickstone states *'In some ways "Graphic Design" has very short history, unlike architecture, the term "Graphic Design" was only really coined in the 20th Century',* the workshop prompts discussion about type development *'through history'.* Digital outputs are often used to present work for review and critique but these are presentations anticipating reproduction through lithography. Pickstone notes with letterpress *'the prototypes are the real thing'*. Students can make decisions about *'…paper stock and mix and test ink, experiment with over printing using the full range of pantone inks: metallics, fluorescents, and pastels and opaque whites.'* Pickstone describes the process as learning: *'discipline, explanation, endeavour and development'.* He recognises in both his own work and that of the students the workshop naturally supports collaborative practice. The disadvantages of letterpress are that the students have to be taught in small groups at GSA 8-10 at a time. The process is slow and there is a significant learning *'attrition rate'*, the number of students who complete inductions but don't return to the workshop. However, for those students who don't choose to use the process again they have acquired an understanding. Pickstone reflects, *'Perhaps not all knowledge gained through practical learning needs to be applied'*. He describes the letterpress workshop as integrated into the curriculum as all the third-year students in *Visual Communication* Illustrators, Designers and Photographers have to compete an assessed piece of work within the workshop.

6. People

As the function of the letterpress workshops have changed between 1967 and 2020 so the experience and the demographic of the those responsible for the workshops has changed. The interviews with staff responsible for the workshops have revealed a range of routes into letterpress and a variety of career journeys. The workshops within Trade Schools of 1960's where characteristically run by male technicians trained as a compositor or printers with commercial experience of working within the print trade. Through the early 1990's there was a period of transition, some technicians retired and others retrained transferring their analogue knowledge of type to digital composition. Today the gender balance is improving,

staff responsible for the 41 of the workshops surveyed to date include 21 female staff and 28 men.

Both *Manchester School of Art* (surveyed in November 2017) and *Plymouth University* (surveyed July 2017) have trained compositors. Paul Collier at Plymouth had begun work as apprentice printer and learnt to set type by hand in a *'jobbing printers'* in Plymouth. He then trained as a *Monotype* compositor before joining the University.

By contrast, Edwin Pickstone at *Glasgow School of Art* (surveyed 2017) has a full-time post which is made up of design lecturer/researcher, designer in residence, and letterpress technician. Pickstone was a student on the *BA Visual Communication Design* course at GSA. During his final year in 2004 Senior Tutor Steve Rigley set a project *'What is the value of letterpress?*'. Rigley's project was both a provocation and invitation. In 2005 he combined technical support with *'Designer in residence'* by a small grant from the *National Heritage Print Fund*. Fraser Ross, the technician who had trained as a compositor working at GSA since 1976 was considering retirement. A combination of wise succession planning and serendipitous opportunity enabled a period of handover and from September 2005 until April 2006 Pickstone worked with Ross. Pickstone recognises the importance of this generational handover, *'…though he didn't have six years to train me, I learnt rigour, and discipline from him…'*.

Chris Wilson at *Northumbria University* views the letterpress workshop as a research *'laboratory'* and has used it as a base his practice-based PhD. He was inspired by a week intensive workshop in the Netherlands with Thomas Gravemaker. Wilson's role is multifaceted: design tutor, researcher and technician. *'the workshop provides students with a historical context for typography'* and does not want *'the workshop to become a museum or window dressing for Open Days.'* It has to be *'a place where students actively make work'*. The *'physicality of type'* provides students who are '*…visually aware, with a way to learn through doing, by designing on the press.'* He identifies the constraints as a positive aspect of letterpress, students can *'Overcome the restrictions of limited number of typefaces and sizes.'* But also acknowledges that some students find it *'Difficult to adjust to both the restrictions and the slow and considered approach to design and composition'* as the cultural conditioning of *'the digital world provides instant gratification'*.

7. Conclusion

This research has surveyed all but three of the letterpress workshops. It has established the number of workshops active in 1967 was 104, this figure has dropped to 44 workshops in 43 Institutions in 2020 (there may be some vestiges of type workshops as yet undiscovered). The research has traced the multiple name changes of the institutions and revealed that only 7 of the 104 institutions have retained their original name from the 1967 listings. Of the 43

institutions with workshops 42 are in the Higher Education sector within post '92 Universities, only *Southport College* in the FE Sector has retained a small element of letterpress. None of the 104 institutions identified on our 1967 list offer any of the print apprenticeships. The 43 workshops located within post '92 Universities are providing courses within Art and Design Schools or Faculties offering BA or MA degrees in *Graphic Design*, *Visual Communication*, *Communication Design*, or *Illustration*, though the workshops in some institutions are used by students from many disciplines. We have established that 41 workshops surveyed to date contain a total of 490 cabinets or type frames, which hold a total of 9,272 cases of type. These consist of consisting of: 8,132 cases of lead type, 1,140, cases of wood type and 22 case of Acrylic type and 84 large presses and 17 table top presses.

The demographic of the staff responsible for the workshops has changed. There are two technical staff who have trained as compositors and printers and the remaining 47 members of staff have learnt to use letterpress equipment through a design education. The nature of the curriculum taught within the workshops has changed radically from the acquisition of technical skills interchangeable skills for the print trade, to a creative workspace which places the student designer at the heart of print design and production. The workshops are today are learning and teaching spaces, research spaces, production spaces, and experimental studios where students can play type letterform and image through the integration of analogue and digital technologies.

Looking to the future we will analyse all the material gathered through the survey, including the equipment survey for each workshop which has yet to be collated. We will continue to conduct phone interviews with staff responsible for the workshop spaces to gain greater insight into links with curriculum and workshops use. We aim to create a digital data base which is likely to list over 9,500 cases of type, and provide press and equipment details. This will provide a listing of typefaces and sizes available in each size per workshop and the catalogue of type held within Education.[2] It is our intention to make the catalogue of presses and equipment an interactive data base and web resource so that institutions can update new acquisitions.

[2] The research may be extended up to Universities outside Art and Design Education which have retained letterpress workshops. *Birmingham University* has moved the letterpress workshop *Winterbourne House and Botanical Gardens* as a working Museum run by volunteers. This workshop has already been surveyed but is not counted in the 44 workshops within Art and Design Education. *Oxford University* has a letterpress workshop in the ground floor of the Schola Musicae of the Quadrangle in the Bodleian Library, whilst *Leeds University* and the *University of Stirling* have workshops which have been revitalised.

Abstract | This paper explores the concept of geometrical frustration as an alternative mode of form-making in design and manufacturing. While builders, craft makers and designers traditionally attempt to work with stress-free materials with predictable response and controlled outcome, nature often develops form and function through mechanisms of stress-informed materials. In biological systems such as flowers, geometrical frustration caused by internal stresses often leads to shape transformation. Although scientists have studied and understood this phenomena, material frustration has yet been introduced as a possibility for designers. In this paper, a frustrated materials approach is brought to the design process, through case studies in two different material systems. Both in ceramics and in latex, the material becomes an active partner in the design process, no longer controlled, predictable and "well behaved". Through close collaboration with the scientist, the material's behaviour is understood and analysed for further exploitation, enabling to reverse-engineer surprising new forms.

KEYWORDS | MATERIALITY, MATERIAL FRUSTRATION, MATERIAL RESEARCH, MANUFACTURING, TRANSDISCIPLINARY DESIGN

1. Introduction

Design and Production are control oriented. The history of design relies on the control over materials through manufacturing techniques such as casting and machining, making sure each chosen matter doesn't "misbehave" (Lefteri, 2012). Processing materials involves external tools and moulds, rules and patterns – all created to ensure order and make sure each material element is passive, thus acts according to plan. The need for control is accentuated by computation capabilities, deeply rooted by now in the design and architecture realm, leaving no room for randomness, aiming at minimal tolerance and maximal efficiency, affecting the whole making of a design project: conception, visualisation, simulation, and fabrication (Carpo, 2013).

The ability to generate practically any imaginable form with ease on the computer screen, with digital design tools and advanced visualisation capacities, has led to the ongoing rising challenge of its materialisation as built or manufactured artefacts; designers and manufactures alike face the challenge of fabrication of complex geometries (Kolarevic, 2005; Austern, et al., 2018); issues of cost, sustainability and geometrical limitations come into play, raising significant barriers. The realisation of complex shapes in large scale, typical to contemporary architecture, is furthermore challenging due to the extensive use of moulds in the fabrication process (Hickert, 2016); It is echoed by the large efforts of research and technological developments in the past decades, oriented towards the development of alternative fabrication methods (Sheil & Glynn, 2011; Menges, et al., 2017). While some concentrate on new technologies, such as 3D printing (Duballet, et al., 2017), other directions of development focus on the opportunities to be found in the material itself. Inspired by the philosophy of new-materialism (Miller, 2018) on one hand, and technological advancement in material research on the other, a rising awareness of matter's generative power is at the centre of design discourse in the past years, under the concept of 'Materiality' (DeLanda, 2015). Seeking innovation and alternative modes of form-making, material-systems are developed, where the inherent capacities of the material itself are enhanced and exploited to achieve performance (Menges, 2012). Such material-centred approach widens morphological expression, promotes efficiency and higher performance, and inherently introduces new design paradigms (Hensel, et al., 2010).

Alternative modes for achieving form and reaching required performance, introducing concepts such as self-organisation, growth, hierarchy, redundancy and resilience, inherently relate to the world of nature (Speck, et al., 2017). In the search for alternative modes of form materialisation, nature serves as a source of inspiration and bio-mimetic development processes. While builders, craft makers and designers traditionally attempt to work with stress-free materials with predictable response and controlled outcome, nature often develops form and function through mechanisms of stress-informed materials (Weinstock, 2010). Wishing to adopt alternative material formation processes from nature, requires a shift from the traditional engineering efforts of balancing and annealing residual stresses

within materials (Withers & Bhadeshia, 2001), to the study of the principles of stress-driven formation, for possible control.

A growing number of bio-inspired material systems are developed in recent years, mostly looking at biological models, extracting their principles of operation and translating those into a synthetic designed realm (Knippers, et al., 2012). This paper presents an ongoing transdisciplinary research that draws its theory and ideas from the world of non-linear physics into the world of design. From the physical formulation of complex form generation and motion mechanisms in nature, an analytical theory was generalised, applicable across scales and materials. This paper will present the application of the theory of incompatible shells on two very different material families, rubbers and ceramics.

2. Material frustration as shaping mechanism

2.1. Learning from Nature

Much of shape transformation in natural system is driven by internal stresses. For example, the opening of a flower, the swimming of a jellyfish and even the beating of our heart, are all driven by the build-up of internal stresses and their release via global shape transformations. The origin of these stresses is *geometrical frustration,* which can be described mathematically. An example that well demonstrates the principles underlying “forming via frustration” is that of the opening of a seed pod. In (Author, 2011) we studied the opening of a dry *Buhinia’s* seed pod. The pod's valves consist of two layers of fibrous tissue, a tissue that expands/shrinks perpendicularly to the fibre orientation upon hydration/dehydration. If the fibres orientation in the two layers would be identical, the entire flat valve would shrink/expand uniaxially, perpendicular to the fibres’ orientation, remaining flat. However, the fibres orientation in the two layers are perpendicular to each other - in $\pm 45^{o}$ to the long axis of the pod. Apparently, this simple micro-architecture of the tissue, is sufficient to drive the valves' twisting in opposite handedness upon drying – a process that "shoots" the seeds to large distances. To understand the twisting mechanism, we note that upon drying, each layer “tries” to shrink uniaxially. Uniaxial shrinkage of one layer with respect to the other, induces curvature aligned with the shrinkage: If the top layer shrinks along one direction, the composed sheet would bend upward along this direction, similarly to a bi-metal ribbon. Therefore, shrinkage in two orthogonal directions in the top and bottom layers, induces a saddle curvature. However, since separately, both layers are flat, their in-plane geometry does not match the saddle geometry (imagine trying to attach a large flat sheet of paper to a saddle). This incompatibility is the cause of geometrical frustration: the valve can either fulfil its natural (or “reference”) curvature (saddle), OR its natural (reference) in-plane (flat) geometry. It cannot be completely relaxed, thus must contain internal stresses. One immediately sees that the same type of frustration can be generated in different ways, in sheets made of different materials: for example, by gluing together two flexible sheets while

they are stretched in orthogonal directions. Like the seed pod, both layers want to shrink uniaxially, in orthogonal directions, i.e., a tendency to form a saddle. This frustrated structure is described in more details in section 3.

Though the tendencies of each separate part of the material are simple and clear, the behaviour of the combined sheet is much more complicated and unpredictable. In order to understand the geometrical and mechanical behaviour of such a frustrated sheet, one has to develop a suitable theoretical modelling.

2.2. Theory of incompatible sheets

Recent developments in the theory of elasticity introduce and develop a new way of thinking, designing and manipulating solids. Within the framework of *incompatible elasticity*, effective theories of rods, plates, and shells were formulated (Efrati, et al., 2009; Aharoni, et al., 2012). In this framework the local intrinsic geometry of a body is expressed with the reference metric and reference curvature. These express the *equilibrium distances* between the elements that compose a solid body. The reference metric and curvature can result from growth, irreversible deformation, or from the geometry and connectivity of the elements that compose the body. The theory expresses the energetic cost associated with deviation from the reference metric (stretching energy) and from the reference curvature (bending energy) (Efrati et al., 2009).

The formalism opened the way to a set of quantitative experimental and theoretical studies of self-shaping sheets (Gemmer & Venkataramani, 2011; Klein, et al., 2007; Santangelo*, 2009;* Author, 2010). Several important notions were determined, based on the new formulation, providing useful *guidelines for the design* of desired shape transforming sheets, often saving the very complex process of solving the nonlinear elastic problem. The theory was successfully applied to many specific structures, including frustrated ribbons with saddle curvature, such as the seed pod described above. Experimental and theoretical study (Author, 2011) demonstrated the ability of the theory to predict a wide range of twisted and helical configurations obtained at different ribbon widths and orientations.

An important notion related to the formalism is "geometrical frustration" (which was mentioned in the previous section). This occurs when the reference metric and curvatures are *incompatible* – they cannot be both realized by a configuration of the surface in 3D. This is manifested by *sharp mathematical constraints,* given by the violation of Gauss-Minardi-Codazzi (GMC) equations. Under such conditions the body will always contain residual stresses. Within the new formalism, the origin of internal stresses is clearly "visible" and the conflicting geometries are clearly expressed.

Frustrated bodies have unique properties. Any cut or change in the shape of their boundaries results in a change in their 3D shape. This is due to the fact that any configuration is a compromise, set by the competition between the reference metric (stretching energy) and reference curvature (bending energy). Any change in the boundaries

of the sheet changes the balance between the conflicting geometries, and a new equilibrium configuration is achieved. This responsiveness and shape variation of frustrated sheets is in a sharp contrast to ordinary stress-free sheets that stay as they are, when cut or curved. This property makes frustrated sheets much more interesting than ordinary ones. A non-trivial information is encoded within them, making them buckle and wrinkle into 3D shapes and to respond in a surprising way to cuts. To some extent such structures are unexpected, but with the theory of incompatible sheets, that holds the information about the reference geometry (in the form of the reference metric and curvature), we can "understand" the frustration of the materials and guess their response.

3. Making form by material frustration: case studies

In mirror of the new physical understanding of generation of complex curvatures in geometrically incompatible, or frustrated plates (Efrati, et al., 2009) and shells (Author, 2011), we developed two experimental design projects: 'Frustrated Materials' and 'Frustrated Ceramics'. These two case studies served as demonstrators of the physical theory, as well as a starting point for future design development. The case studies described in this section operate in two very different material realms, demonstrating the application of similar sets of principles, which rely on the generalised theoretical basis of incompatible shells. From surface design in latex, a soft and flexible material, to morphology in ceramics, a malleable material but brittle once fired, the two case studies will demonstrate the agency of material frustration.

Figure 1. Frustrated Material', 31 latex tiles. Bet Binyamini, September 2018. (photo: Shay Ben Efrayim).

3.1. Frustrated materials

Frustrated Materials' is a composition of 31 latex tiles (36x36cm each), forming an ornamental wall-piece (Figure 1). Latex is an elastomer, used here in the form of thin (cast) sheets. It is a continuous, homogeneous and isotropic material, with a typically high stretching capacity. Here, this capacity was used to introduce directionality in the material, stretching the latex sheet to one direction only. By the bonding of two sheets, stretched in perpendicular directions, we introduced geometrical incompatibility in the system, as described in section 2. The two stretched and connected latex sheets make a bi-layered material that is frustrated, each layer tending to shrink in opposite directions. Attached to a frame and geometrically incompatible, the bi-latex surface is charged with energy. Once incisions are introduced on the surface, the stored energy is released through the spontaneous generation of three-dimensional shapes. The articulated and ornate surfaces of the 'Frustrated Materials' tiles were made by laser-cutting of different patterns, of stretched bi-layered latex material. To accentuate the bi-layer effect, we chose a top layer of uniform cream colour, and a bottom layer of varying colours (Figure 2).

Figure 2. Surface design by material frustration. The bi-layer structure is accentuated by the choice of contrasting colours between the layers (photo: Shay Ben Efraim)

The case study explored the design potential of controlled shape generation in the bi-layered latex surfaces, through the variation of a few elements. The effect of three main parameters can be demonstrated through the work:

Radius of curvature of the surface - Three elements are related (Efrati, et al., 2009): curvature (K) of the surface (expressed as $1/r$), thickness (t) of the material, and the differential strain (ε) (unitless, $\frac{\Delta L}{L}$as the percentage of stretch of the material), expressed as

$$K \cong \varepsilon/t \text{ or } r \cong t/\varepsilon$$

This formulation indicates that the typical radius of curvature of the shapes that would form by the cutting of a frustrated surface, could be directly dictated by the thickness of the material used, and the amount of stretching applied (applicable as long as the material is considered 'thin surface' physically). Through a short series of samples, we identified a typical radius of curvature that would be expressive and enabling: significantly visible curvature, without reaching strongly curved forms. Based on a series of initial tests, we aimed for a typical curvature diameter of 8-10mm, being expressive, while not too curly. As we used a latex thickness of 0.4 mm, (the total thickness (t) being 0.8mm), we aimed for a differential stretching (ε) of around 15-20%, that would result in typical curved shapes of 8-10mm diameter, identified as our desired range (Figure 3). (A stronger stretch resulted in more curly or highly twisted shapes, a weaker stretch would result in less pronounced curvature, closer to flat surfaces).

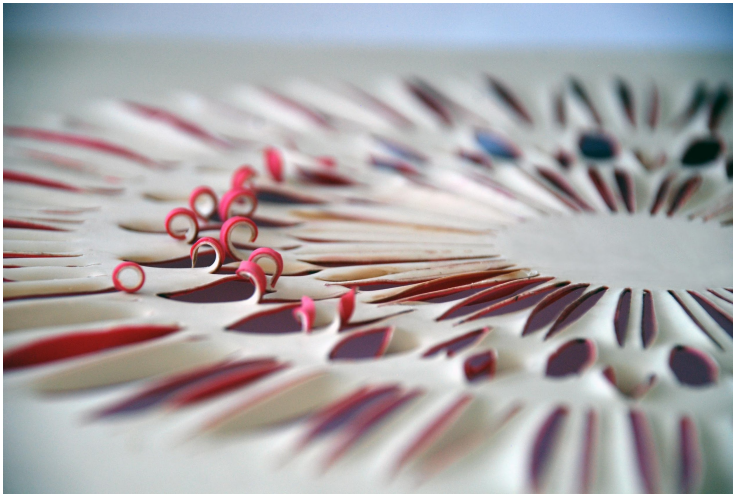

Figure 3 Selecting the radius of curvature by the amount of stretch applied over the material (according to given thickness).

Orientation over the surface - The scientific work of (Author, 2011) showed that the frustrated sheet tends to bend into a saddle-like configuration. The shape of strip cut strip out of this surface would vary according to its orientation over the surface (angle θ with one of the stretching directions), acting as a portion of a saddle-like curved surface, i.e. an identical cutting curve would generate different shapes, depending on its orientation over

the sheet (θ) (Figure 4). Following that principle, the 'Frustrate Material' tiles were designed with mandala-like patterns, all with radial organisation. The radial array of an identical cutting curve, was used to express the variety of shapes that form out of the same cutting curve, placed in different orientation: from cylinder-like shapes in either direction of the stretching (θ=0/90), to saddle-like or helical ones on the biais direction ((θ=45), with an identically repeating curve.

Geometry - (Armon, et al., 2011) have demonstrated both empirically and mathematically that strips cut on the biais orientation ((θ=45) demonstrate two different regimes: "narrow" strips that twist around a straight centreline, and "wide" strips that form helical configurations, as a cut out from a cylindrical envelope. The transition between narrow-strip and wide-strip behaviour was explored in the case study, through the variation of patterns in the tiles. Starting with a set of basic graphic elements that generated different shapes, we established a set of "building blocks", or "letters", with which an infinite variety of patterns could be composed.

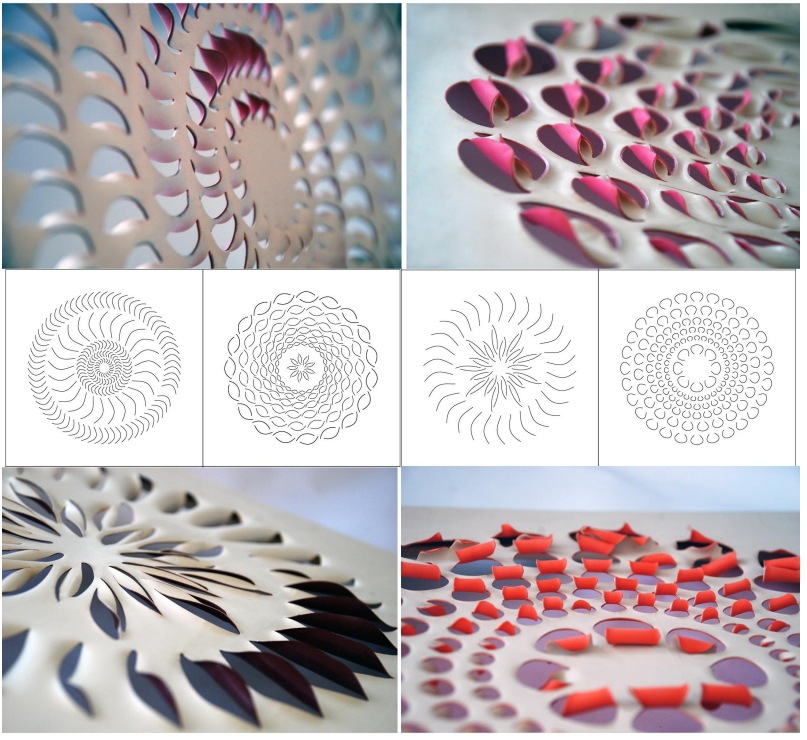

Figure 4 - Rotational patterns accentuating the effect of orientation on the surface over the resulting shape.

The rotational “mandalas”, along with the biological references of frustrated formation of leaves and petals, have led us to the theme of flowers as the visual concept for the tiles. The patterns were conceived with regards to a flower type (Dahlia, Sunflower, Carnation, Thorn, Chrysanthemum etc.) (Figure 6) planning its three-dimensional outcome by using the “building blocks” that we have established in earlier stages (Figure 5). ‘Frustrated Materials’ can be considered as one whole piece and at the same time as a series of tiles; it is a showcase for the scientific work, while being the seed for creative design exploration.

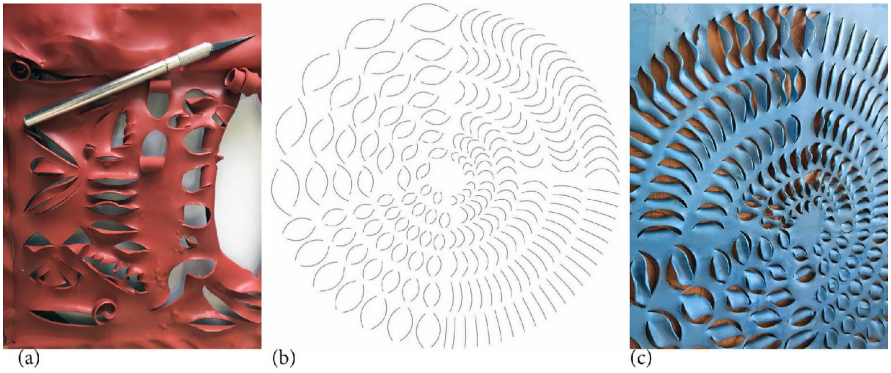

Figure 5. Developing patterns (a) manual cutting, creating a catalogue of ‘building blocks” (B) polar array of curves, developing rotational mandala, pattern (c) surface.

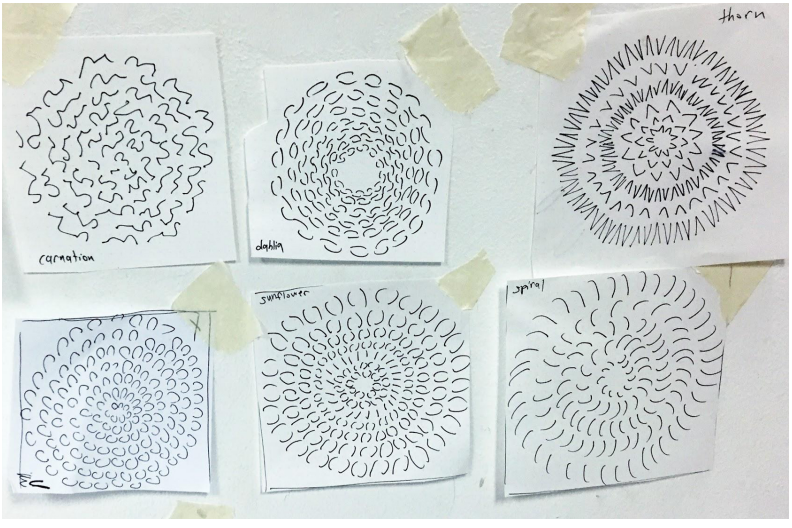

Figure 6. Drafting biologically inspired 'flower mandalas' as inspiration for digital design

3.2. Frustrated ceramics

Figure 7. Series of ceramic material exploration, seeking to accentuate displacement and curvature of the ceramic surface, observed as maximal Z value and minimum radius of curvature

'Frustrated Ceramics' is a series of material explorations that takes the case study of 'Frustrated Materials' as its starting point. Here too, frustration is induced in a bi-layer material, enhancing its natural properties. In the basic ceramic manufacturing process, from the humid chunk of matter (the 'ceramic body') to the accomplished, dry and brittle final stage of the artefact, firing and drying play an essential role. Gradually, water and humidity are released out of the ceramic body in the drying phase, to be then heated in a kiln to bring the clay-body to its full maturity. As moisture evaporates, clay particles come closer and closer together, and thus shrinkage occurs . Shrinkage is substantial in the firing process as well, as glass begins forming within the clay particles (platelets), filling cavities and voids, and reducing volume. The amount of shrinkage is affected by several factors such as type of clay, size clay particle, weight, proportions, size of piece exposure to air, and more. Radical differences in shrinkage within a single piece would lead to the build-up of internal stresses, and are therefore carefully avoided by ceramists, as these might lead to cracking (Reijnders & Centre, 2005).

Wishing to induce frustration in the ceramic material, we utilised the shrinkage phenomenon, inherent to the ceramic process. We combined two material types with

substantially different shrinkage rate, porcelain (Audrey 12.5% shrinkage) and stoneware (Terrazo Umbra, 7% shrinkage), bonded to act together as material of bi-layer architecture. The different shrinkage rates within the material introduce geometrical incompatibility (Figure 8) in the system, inducing residual stresses and resulting in large displacements. A flat bi-layered piece entering the kiln for drying and firing process, resulted in a three-dimensional ceramic form (Figure 8). While in the latex bilayer [see 3.1] the material was anisotropic, with directionality introduced by stretching, forming a surface of negative Gaussian curvature (anticlastic), the ceramic material is isotropic and incompatibility between the layers is uniform, forming a surface of positive Gaussian curvature (synclastic).

Figure 8. Flat rectangles of ceramic-body entering the kiln for drying and firing (b) resulting three-dimensional shape.

Aiming to achieve significant displacement to create morphology and maximum scale, series of samples were realised to identify the effect of different parameters over the resulting shape. Parameters related to the ceramic process, such as level of humidity of the ceramic body, positioning in the kiln and the drying-firing curve were examined for their effect over the resulting objects. Scientific principles were implemented through the exploration of geometric properties, such as thickness of the layers, width-length ratio of the element, curvature continuity of the two-dimensional contour and surface grooves, were varied to analyse their effect over the resulting form.

- **Minimal thickness -** similarly to the prior case study, here too the thickness directly affects the curvature obtained by the surface; the thicker the material, the shallower the curvature would be. However, compared to the latex, the wet clay is heavy and soft. This makes gravitation effects non-negligible. Gravity enters the scene, and should be taken into consideration, limiting the amount of curving of large samples. Therefore, we aimed at minimal thickness of the bilayer, within the possible range of the clay material (typically, 2-4 mm for each layer).
- '**Narrow ratio' - length to width -** In relation to the overall thickness and gravity, another geometrical consideration would be the ratio between the circumference and the surface area, i.e. the width to length ratio of the piece. The narrower the

piece, the smaller the frustration is; the conflict between lateral flatness and curvature is minimised. A more significant curvature in the long direction can take place, which is only weakly “resisted’ by the tendency to flatness of the in-plane geometry (the reference metric) (Figure 10). We therefore prioritized narrow and long geometries, to achieve significant morphologies.

Figure 9. From flat sheets to shaped ceramic, illustrating geometrical incompatibilities: the matching curves in the flat sheet transform to non-matching edges once frustration is in play.

- **Oscillating curvature** - A large number of shapes can correspond to the definition of long and narrow. We have noticed that the geometry of the contour of the shape affects the obtained curvature of the surface, and a clear preference was noted to outline curves that had oscillating curvature, forming a kind of S shape (Figure 11). While this behaviour was clearly observed in samples, its origin is still unclear from the theoretical point of view and is the subject of new mathematical and physical research at the lab these days.

Figure 10. Prioritising long and narrow shapes where lateral frustration is reduced, and significant curvature can take place in the long direction.

- **Introducing grooves** – Due to the isotropy of the ceramic material, the incompatibility within the ceramic surface is homogenous, hence restricting curving as mentioned above. In order to accentuate curving, we introduced directionality in the material through grooves in its stoneware layer, as this layer restricts the movement of the material (as a result of lower shrinkage rate) (Figure 11). Whether inspired by the mechanical reference of a hinge, or biological reference of fibres in the seed pod (see 2.1), the grooves enable movement on the perpendicular direction to the groove, and thus accentuate the curving on this direction.

Figure 11. Oscillating curvature of two-dimensional contour curve creates significant displacement in resulting surface. Grooves on the terrazzo layer enable additional displacement and curvature.

4. Discussion

This paper presents the implementation of frustrated materials as an alternative approach to design and fabrication, through two case studies, in ceramics and soft materials. Although the principle of materials frustration is common in biological systems, known and understood by scientists, it has not yet been introduced to designers as a possible means of creation. By working from the materials' properties, this proposed approach could come as an alternative to the efforts invested in shape generation, creating form becomes simple through a reverse engineering process, once leaning on scientific knowledge. This approach brings new players into the design process: the material becomes active and sometimes surprising and the designer, who works closely with the scientist, no longer forms it alone. Therefore, there is a need for mapping and reorganisation of the design process, which may lead to an alternative methodology and even a new role for designers.

Making by material frustration, suggests a new form of manufacturing. Rather than technological advances it enhances material inherent capacities. Free from moulds, manual labour or new technologies, it suggests an alternative forming process, offering freedom of shape and opening new morphological horizons as well as a detour to serial production. In ceramics, as explored in the second case study, material frustration suggests an alternative to traditional form-making of vessels and may lead to more sustainable possibilities of manufacturing by reducing excessive labour, large quantities and stock.

By reflecting on these two different projects, materials frustration for design may be analysed further in order to outline an alternative design methodology. Frustration may also offer new capabilities for traditional materials. In latex, for example, by generating frustration, structure was introduced to a flat, isotropic, structureless material, thus enabling the material autonomy. Further investigation in the potential of frustrated materials in design could open more possibilities for innovation in materials yet to be explored, such as glass, wood, metals and more.

For designers, utilising frustration in materials requires a shift of control: taking a step back from the drawing board or computer screen and enabling the material properties to lead the way. Following hands-on materials experimentation and research, the design potential of the materials' behaviour may be analysed and later translated for further development - as a bottom-up strategy for design. This strategy not only affects manufacturing methods but may also hold potential for creating original shapes and forms, difficult to foresee or plan in standard approaches. Here, the material is no longer a passive matter which reflects exactly the designer's ambitions. Therefore, this proposed method impacts the role of the designer who should embrace a flexible mindset and reflexive attitude while gaining knowledge of the frustrated material's behaviour, which is sometimes surprising, unexpected and even difficult to understand. A third party, the physicist, can be joined as someone who understands the materials' frustration (knows the principles of the theory of incompatible elastic sheets) and can help the designer with his/her interaction with the material. Once understanding the qualities of the material, the designer may strategically intervene in the process in order to exploit the frustration for the desired results. In the process described in these two case studies, the designer may be seen as an agent, connecting between different partners: expert, materials and tools, to explore innovative ways of making.

Material culture(s). Research paths in an evolving material design culture, and the connected future designer's attitudes

Doriana Dal Palù*[a], Beatrice Lerma[a], Claudia De Giorgi[a]

[a]DAD – Dipartimento di Architettura e Design, Politecnico di Torino
*doriana.dalpalu@polito.it

Abstract | This contribution will investigate how material design culture is evolving: in fact, as designers, we can choose materials taking into account their variety during the design process, as well as design them. The article, through the analysis of a first exploration of just some of the most active and innovative academic case-study laboratories, in which tests and experiments on innovative materials for design are performed, will highlight the most recent research directions covered by designers in the new materials world: growing and living materials, DIY materials, active materials, materials in the circular economy, manufacturing processes applied to innovative fields and innovative ancient materials, rediscovered from the past and re-launched in the next future will be discussed. Those trends will be investigated to outline the directions of designer's and research group's activities and their new attitudes on the topic.

DESIGN BOUNDARIES; MATERIALS EXPERIENCE; MANUFACTURING PROCESSES; MATERIAL DRIVEN DESIGN; MATERIAL ACTIVISM

1. Expanding the horizon of the materials for design

Materials, as underlined by many authors (Ashby, Johnson 2009; Karana, Pedgley, Rognoli 2014; Karana et al. 2015; Miodownik 2014), are the essence of what matters just as the choices made by the designer when contriving conscious products. Expanding the horizon of research and experimentation activities that designers constantly perform, some emerging phenomena can be highlighted within the wide world of materials for contemporary design dictated by the hybridization between different disciplines, from the birth of a "scenario founded on the collaboration between design and science" (Ito 2016; Langella 2019) and also from the changes that the production processes have undergone, thanks to the evolution of some specific technologies: the researches on materials for design are as wide as ever and offer a broad spectrum of opportunities for achieving new material experiences in design (Karana et al. 2019). This contribution will investigate how material design culture is evolving: in fact, as designers, we can choose and feel materials taking into account their variety during the design process, as well as design themselves.

In recent years, the value of craftsmanship has grown significantly: this revaluation and re-flourishing of craftsmanship (Bardzell et al. 2012), or of those who have a deep connection with the material world and can "dominate a dialogue between knowledge abstract and practical", is parallel to the spread of the maker (and Fab Labs) phenomenon who, according to Richard Sennet (2013) responds to the need (of many designers) to regain possession of the surrounding world through an active experience, a material comparison with it (Miceli 2012).

Hard experimentations, biological methods and systems found in nature are applied to the study and design of engineering systems and modern technology: these are examples of how designers and other experts in different disciplines can collaborate to transform the matter and modify it at will: Synthetic Biology and Living Technologies are some of the disciplines in which man tries to produce “natural” materials and to face some of the key sustainable challenges of the 21st century.

On the other hand, the experiments in the families of DIY (Do It Yourself), cooked materials and open materials are characterized by subtle and labile boundaries: according to the principles of molecular gastronomy and alchemy (but also of botany and biology), today’s designers are able to produce new materials for the project through new or renewed processes starting from industrial production waste, materials from plant sources (plants and fungi), animal sources and bacteria, traditional materials, such as wood or stone, and many others.

3D printing latest interesting frontiers go beyond the traditional 3D printing process: experiments have been carried out with food, ceramic and stone materials, but also for architectural fabrication. Sugar, waste polymers, flexible elastomers, organic mixtures, stone or glass can all be 3D-printed, thanks to a consolidated and renewed technology, by the use of new materials for the production process. And thanks to this technology and other

production and design processes, defined and cared for by interventions and design, they give a new shape to traditional materials and ancient arts.

Materials from the past, from local and ancient traditions are becoming more and more new future materials: an archaic material library that is still not set, should instead be conceived in the next future in Politecnico di Torino, investigating the ancient natural resources, artefacts and everyday practices of a specific area. Materials and cultural heritage, the core essence of typical territories that are disappearing or that have been forgotten by time, could be oriented to innovative and speculative further design developments.

2. Today's places of experimentation: the laboratories

In a new, more blurred vision of disciplinary boundaries, known as “The Age of Entanglement” (Oxman, 2016), the point of view changes: the focus of the materials designers – including that of manufacturers – is no longer primarily oriented towards the final application, but is increasingly curiosity-driven, i.e. guided by the pure and simple curiosity of researching, experimenting and observing the material.

The gym in which designers increasingly test the crossroads of knowledge in the matter of materials for design is represented by experiences gained during graduation theses and PhDs or – in the case of in-house designers – during their continuing education outside the company, working in interdisciplinary laboratories within universities or experimenting during workshops and summer/winter schools in close contact with artists, scientists and professionals in various fields. The research tools change too: books and scientific journals are abandoned and ecomuseums, pots and pans and microscopes are rediscovered, along with waste deposits and blogs. The following overview represents a first exploration of just some of the most active and innovative academic case-study laboratories, in which tests and experiments on innovative materials for design are performed. A selection of the most up-to-date laboratories is presented with a brief description that leaves room for the original presentation words of the team, accompanying it with the university or research body that hosts it, the country of origin, the name of the laboratory coordinator and the website, for further investigations, and a short overview on the originality of each approach.

2.1 Hybrid Design Lab

Università degli Studi della Campania “Luigi Vanvitelli”, Naples (Italy) [Prof. Carla Langella]

> “Hybrid Design Lab is a research, design, and teaching laboratory geared towards testing the relationship between design and science. The lab is oriented to experience the opportunity to integrate advanced research, teaching and production through science-inspired design. One of the main objectives is to transfer the theoretical and experimental research in the areas of biological sciences, new materials and new technologies, to the design dimension of the sustainable

> innovation of products and services. The ability to spread through common products, and preferably daily, new knowledge and sensitivity on the environment, human health and on social equity, offers new prospects for real and tangible improvement of quality of life and growth of awareness, precisely because based on large numbers and, therefore, a large impact. The HDL is based on the integrated processes that underlie the life of biological systems and the balance of their ecosystems. Birth, life, death and re-integration in the natural cycles become references to proposal design production, process and strategies for the recovery of resources, innovative, yet environmentally and socially sustainable."
>
> (http://www.hybriddesignlab.org/, accessed on February 13th 2020)

In Hybrid Design Lab, the original approach arises from the new and unprecedented prospects of *intersection between scientific knowledge and design culture*.

2.2 MakeGrowLab

Puławy (Poland) [Dr. Roza Janusz and Dr. Josh Brito]

> "The project began with one question: What if we could grow materials instead of making them and at the end of their cycle, use it as fertilizer which would then be used to continue the cycle of a biological production system? The MakeGrowLab now consults, designs and produces bio-materials for mission-driven companies. The goal is to mimic the symbiotic processes of nature, to not pollute the environment but enrich it instead. They aim for The Biorevolution Movement - to fuse science with design, to create a fully circular production of local, sustainable materials and spread it around the world. The inspiration derives from the symbiotic processes of nature, specifically the life-cycle of plants, where there is no waste and everything is recycled. Since 2019 the team is growing with Future Farmers from different backgrounds but with the same goal: to spread The Biorevolution."
>
> (https://www.makegrowlab.com/, accessed on February 13th 2020)

The MakeGrowLab key-element of innovation is *thinking the material as a living element*, able to born, grow, live and die, exactly like any other living beings.

2.3 Design and Living Systems Lab

Central Saint Martins, University of the Arts London, London (United Kingdom) [Prof. Carole Collet]

> "The Design and Living Systems Lab is a pioneering research laboratory that explores the interface of biological sciences and design to challenge established paradigms and envision new sustainable materials and forms of production for the future. The Lab explores a new hierarchy of relationships with the 'living' where designers operate within a sliding scale of a 'natural nature' and a new 'programmable nature' in the quest for innovative ecological design and fabrication models. The main objective is to explore biological sciences through design to grow new design

> propositions that could facilitate the transition to the 'one planet living' horizon 2050. Not only we are beginning to explore the advantage of biological systems in terms of zero waste, minimum use of energy and materials, but with synthetic biology, scientists have developed means to bio fabricate like 'Nature' does. We can program and engineer living organisms to grow tailored materials. Such extraordinary tools can trigger a paradigm shift in terms of design and manufacture for the future."
>
> (http://www.designandlivingsystems.com, accessed on February 13th 2020)

In the Design and Living Systems Lab design is seen as a *proposer of innovative fabrication models*, able to set potential speculative scenarios.

2.4 Mediated Matter

MIT Media Lab, Boston (U.S.A.) [Prof. Neri Oxman]

> "The Mediated Matter group focuses on Nature-inspired Design and Design-inspired Nature. It conducts research at the intersection of computational design, digital fabrication, materials science and synthetic biology and apply that knowledge to design across scales from the micro scale to the building scale. They create biologically inspired and engineered design fabrication tools and technologies and structures aiming to enhance the relation between natural and man-made environments. The research area, entitled Material Ecology, integrates computational form-finding strategies with biologically inspired fabrication. This design approach enables the mediation between objects and environment; between humans and objects; and between humans and environment. The goal is to enhance the relation between natural and man-made environments by achieving high degrees of design customization and versatility, environmental performance integration and material efficiency. The group seeks to establish new forms of design and novel processes of material practice at the intersection of computer science, material engineering, design and ecology, with broad applications across multiple scales."
>
> (https://mediatedmattergroup.com/, accessed on February 13th 2020)

In the Mediated Matter group, a step back to *natural processes intertwined with current production processes* informs the new Material Ecology culture.

2.5 [MI] - Material Incubator

Centre of Applied Research for Art, Design and Technology (CARADT), 's-Hertogenbosch (The Netherlands) [Prof. Elvin Karana]

> "Material Incubator is a creative research lab that explores the potentials of materials from living organisms for an alternative notion of the everyday.
>
> Bringing together researchers and practitioners from different schools, Material Incubator [MI] encourages tangible interactions with the living organisms, such as

> algae, fungi, plants and bacteria, to explore and understand their unique qualities and constraints through diverse technical and creative methods taking artists, designers and scientists as equal and active partners in the material creation. The core research team of the MI includes artists and product designers specialised in bio-design, (digital) storytellers and micro-biologists.
>
> In exploring and designing for an alternative notion of the everyday from materials from living organisms, the [MI] researchers ground on the theory of Materials Experience, which suggests that whilst our experience with an artefact may originate from - or be moderated by - a wide variety of sources, one of the prominent sources is its physical reality, i.e., its material(s)."
>
> (https://www.materialincubator.com/about, accessed on February 13th 2020)

Material Incubator [MI] sets its original approach on a *co-creation process between different expertise*, within whom the design is a participant of the co-creation, and the new matter is the possible output.

2.6 Self-Assembly Lab

MIT's International Design Center, Boston (U.S.A.) [Prof. Skylar Tibbits]

> "The Self-Assembly Lab is a research lab at MIT inventing self-assembly and programmable material technologies. Self-Assembly is a process by which disordered parts build an ordered structure through only local interaction. In self-assembling systems, individual parts move towards a final state, whereas in self-organizing systems, components move between multiple states, oscillate and may never come to rest in a final configuration. The Self-Assembly Lab is located in MIT's International Design Center, a cross-disciplinary design research centre. The Singapore University of Technology and Design was established in collaboration with MIT to advance knowledge and nurture technically grounded leaders and innovators to serve societal needs. This will be accomplished, with a focus on Design, through an integrated multi-disciplinary curriculum and multi-disciplinary research."
>
> (https://selfassemblylab.mit.edu/about, accessed on February 13th 2020)

In the Self-Assembly Lab the *design process is informed by mathematics, physics, robotics and digital technologies*, following a "techno-creative" approach.

2.7 Material Experience Lab

Technische Universiteit Delft (TU Delft), Delft (The Netherlands) and Politecnico di Milano, Milan (Italy) [Prof. Elvin Karana and Prof. Valentina Rognoli]

> "Materials Experience Lab is a cross country research group bringing together researchers/practitioners who introduces unique ways of understanding and designing (with) materials to radically change and enhance the relationship people have with materials and artefacts. The lab introduces unique ways of understanding and designing (with) materials by combining research methods, techniques, and

> tools from product design, social sciences, materials science, and engineering. The term 'materials experience' describes the holistic view of materials in design, emphasising the role of materials as simultaneously technical and experiential. In most of the research activities, the Materials Experience Lab combines interpretive and empirical research techniques in a unique iterative manner, actively promoting a Do-It-Yourself (DIY) approach to materials that pushes the boundaries of material (driven) design. The DIY approach to materials brings people and materials closer in the making, promoting further consideration of contexts and time in designing, making, and use, greater awareness of the resources required, greater agency for working with materials, all of which leads to novel design outcomes."
>
> (http://materialsexperiencelab.com, accessed on February 13th 2020)

In the Materials Experience Lab, the *direct experience of the matter* is the key point of the new materials development, with a "creating-by-doing" approach.

2.8 Institute of Making

University College London (UCL), London (United Kingdom) [Prof. Zoe Laughlin and Prof. Mark Miodownik]

> "The Institute of Making is a multidisciplinary research club for those interested in the made world. The mission is to provide all makers with a creative home in which to innovate, contemplate and understand all aspects of materials and an inspiring place to explore their relationship to making. At the heart of the Institute of Making is the Materials Library – a growing repository of some of the most extraordinary materials on earth, gathered together for their ability to fire the imagination and advance conceptualisation. A place in which makers from all disciplines at UCL can see, touch, research and discuss, so that they can apply this knowledge and experience to their own practice. Alongside the collection is the Makespace – a workshop where members and guests can make, break, design and combine both advanced and traditional tools, techniques and materials. The facility brings together equipment, expertise and perspectives of making from a wide range of disciplines, encouraging users to engage in the craft, design, technology, history, philosophy, art and engineering of making."
>
> (https://www.instituteofmaking.org.uk/, accessed on February 13th 2020)

The original approach at the Institute of Making lies on a *makers community*, in which the exchange of knowledge between peers is fundamental for generating new know-hows.

2.9 Material Design Lab

KEA - Copenhagen School of Design and Technology, Copenhagen (Denmark)

> "Material Design Lab consists of The Box, The Lab and The Library. The Box is a walk-in expandable box that contains an exhibition of raw materials. It is the starting point to a basic understanding of the 'raw ingredients' before they are processed and

mixed. The Lab itself is the heart of Material Design Lab and resembles a hybrid between a design prototyping workshop, a scientific laboratory and an industrial kitchen. It is a space designed for materials to be tested, manipulated, refined and potentially, for new ones to be created. The library is the Material ConneXion Copenhagen collection containing 1500 material samples, as well as access to the online database providing detailed information on over 7500 materials. The library also holds a wide range of books on materials relating to design and architecture."

(http://materialdesignlab.dk/, accessed on February 13th 2020)

Understanding and knowing the raw materials that are at the basis of the materials that we experience every day is the original approach at the Material Design Lab.

2.10 LAMA - Ancient Materials Analysis Laboratory

IUAV University, Venice (Italy) [Prof. Fabrizio Antonelli]

"The Ancient Materials Analysis Laboratory was created in 1993, with the aim of carrying out didactic, research and service activities for third parties in the field of stone and lithic materials used in ancient times. The extraordinary technological development of the last few years has made science previously unthinkable progress, and therefore also the acquisition of a large mass of data on the historical-artistic materials of cultural heritage in general, data that are of significant interest for the characterization, dating and conservation of the cultural heritage itself. The institutionalization of the above teachings, as well as archeometry, geoarchaeology, and various other disciplines such as chemistry or physics applied to conservation science, as well as the creation of associations and specialized journals, among other things with specific tasks promotional, has finally positively changed the national panorama in this sector of applied sciences."

(http://www.iuav.it/SISTEMA-DE/Laboratori3/, accessed on February 13th 2020)

A reference to the *materials of the past to understand the materials of today* is the key point to the approach of the Ancient Materials Analysis Laboratory.

2.11 Wearable Technology Lab

University of Minnesota, St. Paul, MN (USA) [Prof. Lucy Dunne]

"The Wearable Technology Lab (WTL) is an interdisciplinary research laboratory founded in 2009. WTL research focuses on the intersection between apparel and new technology: for instance, in expanding garment functionality through dynamic geometry and new sensing functions; in improving the way we use, manage, and consume clothing; and in streamlining the design and manufacturing processes of smart clothing and e-textile products. New technology opens new frontiers in understanding the human body, mind, and capability through pervasive sensing, actuation, and interaction. Many projects deal with translating technological potential into the real, everyday world: understanding human physical and

> emotional comfort and balancing these variables with trade-offs of performance variables in a smart system design."
>
> (https://wtl.design.umn.edu/, accessed on February 14th 2020)

The *intersection between new materials, new technologies and the world of wearables* is the meeting point of the Wearable Technology Lab, where new intelligent and active "skins" are conceived.

2.12 Smart Textile Design Lab

Swedish School of Textiles, University of Borås, Borås (Sweden)

> "At the Swedish School of Textiles creativity and theory are combined with practical work in several machine parks and laboratories. The unique with the educational programmes is that students and researchers have the opportunity to work with the entire process, from hand knitting machines to advanced 3D techniques, from hand weaving to effective weaving machines. Students and researchers also have the opportunity to elaborate with colours and different types of coatings in the colour lab, to use pattern construction the traditional way or use the latest computer programmes. The well-equipped sewing room gives almost unlimited possibilities. The Smart Textile Design Lab turns textile traditions and materiality upside down; the researchers develop, explore, and experiment with new expressions for textiles through the use of various technologies and textile techniques."
>
> (https://stdl.se, accessed on February 14th 2020)

The process, from dyeing to knitting to sewing, is the main core of the Smart Textile Design Lab, where *innovation is the reinterpretation of traditional and well-established techniques and processes*.

As already introduced, this overview doesn't want to be exhaustive, it rather outlines how the matter of material design is evolving in new material design cultures, thanks to the collaboration with different disciplines and know-hows, and new approaches, producing heterogeneous materials belonging to some possible clustered trends.

3. The consequent new material design cultures

The article, through the analysis of substantial case studies of the most recent and academic laboratories, in which innovative materials for design are tested and developed, highlights the most recent occurrences and research directions covered by designers in the new materials world: materials in the circular economy (i.e. from circular materials to urban mining); growing and living materials; DIY (i.e. Do-It-Yourself) materials and material tinkering approach; manufacturing processes such as 3D printing applied to innovative fields

(e.g. food, stone, architecture, etc.); innovative ancient materials, rediscovered from the past and re-launched in the next future.

It should be pointed out how designers feel the need to "compose, modify, transform, and self-produce their own materials" (Rognoli, Ayala 2018), by using ancient materials and new technologies, by modifying traditional materials, waste materials, bacteria, vegetables (see Figure 1)(Karana et al. 2019; Ayala-Garcia, Rognoli, Karana 2017).

Figure 1. Biolace, Carole Collet.

For example, Blood Related (Figure 2) is a material that uses waste materials, a zero kilometre, for the production of new raw materials. Awarded at the Dutch Design Week in 2018, it is a compound material, printable like plastic, selected by dried and pressed cow blood: waste from the meat and livestock industry, they become raw materials and we are asked about the limits of what can be transformed and be matter. Moreover, as underlined in the introduction, designers, alchemists and cooks experiment the production of self-produced materials from vegetable sources: the principles of molecular gastronomy and methods, the techniques of self-production, individual or collective, are the tools for the creation of new democratic materials, accessible and with a low technological impact (Rognoli, Ayala 2018; Rognoli et al. 2015; Rognoli, Ayala, Parisi 2016a; 2016b; Parisi, Rognoli, Sonneveld 2017). On the other hand, the materials grow and transform themselves within laboratories (Figure 3): “we can grow all kinds of structures using living organisms, from foams that can replace plastics in footwear, to leather-like materials without animals. Furniture, flooring all are currently being prototyped. Fungi are able to grow materials that are naturally fire retardant, without any chemicals” (Lee 2019).

Figure 2. Blood Related, Basse Stittgen.

Figure 3. Packaging film from bacteria, MakeGrowLab.

While many of these activities are currently conducted on an experimental and extemporary basis, this does not mean that the approaches to research are not based on a solid scientific framework. Exploring the way that other professionals work and trying to "tune in" with their skills, sometimes borrowing their methods, helps not only material designers but also manufacturers to break free from prefabricated schemes, pursuing new currents and new avenues of research. The new figure of the materials designer is therefore more and more

outlined by ephemeral and blurred “boundaries”, coherently with the contemporary Design condition: in those laboratories, the designer turns himself into new professionals characterised by a hybrid knowledge, driven form different know-hows. We can therefore discover a “designer-maker”, a “designer-archaeologist”, a “designer-biologist”, a “designer-detective” and a “designer-alchemist”, following the latest materials culture trends (De Giorgi, Lerma, Dal Palù 2020). These and other emerging issues coming from the materials design culture are currently investigated by the authors of the present contribution.

Mind-mapping in design culture: A tool for ideation in graphic design education?

Dr Phil Jones, Marion Morrison,

Arts University Bournemouth
pjones@aub.ac.uk, mmorrison@aub.ac.uk

Abstract | This study focuses on mind-maps as an aspect of design culture – the conventions and practices adopted by a community of designers. The research aims to work towards establishing the effectiveness of mind-maps as a tool for ideation. It questions the extent to which mind-maps enable students to break away from the cultural frames evoked by design briefs in order for creative cross-space associations to occur. By comparing mind-map-like diagrams produced by nine undergraduate students with codes emerging from the analysis of the corresponding briefs, the study seeks to answer the question: What levels of cross-space mapping are evident in the knowledge representation diagrams produced as part of an undergraduate graphic design, practice-based project? The study found 301 cases of internal linking, as opposed to 23 instances of cross-space mapping, however it concludes that there is value in knowledge representation diagrams for ideation and makes recommendations for their use.

KEYWORDS | MIND MAPS, CREATIVITY, KNOWLEDGE REPRESENTATION, FRAME THEORY, CONCEPTUAL BLENDING

1. Context.

As lecturers, both researchers worked on the BA(Hons) Graphic Design course at the Arts University Bournemouth. The project grew out of a conversation in which we both expressed a scepticism with regard to the value of mind-mapping as a method for ideation. Despite our scepticism, it was noticeable that mind-mapping was a feature of many students' work. We questioned whether this practice had become part of a "project culture" or "la cultura di progetto" (Julier, 2004, p.6) instilled through prior educational experience. Conversely, there are claims for the facility of Mind Maps™ and concept maps in the literature. Novak and Gowin (1984, p.17) state that, "concept mapping may be a creative activity and may help to foster creativity". Whereas Buzan and Buzan (2010, p.93) include being "able to create new associations from existing ideas" as a key feature of Mind Maps™.

The students' use of mind-mapping, together with such claims above, raised questions: were we undervaluing the usefulness of mind-mapping? What value did students attribute to this method? Or more simply, "What's happening here?" (Glaser, 1978).

Our conversations occurred during the assessment of fifteen submissions that were later entered for the International Society of Typographic Designers Student Assessment Scheme. These provided the sample for the research, the ISTD briefs were also included as data. Prior (cited in Charmaz (2014, p.45), notes how researchers can address what documents *do* as well as what they *contain*. These mind-maps, as part of the unit submission, and in relation to the ISTD scheme, are assessed. We should therefore acknowledge that what the mind-maps might do is present a systematic and smooth process of development in order to acquire marks. Another possibility is that they do little but are used unthinkingly; replicating previously instilled behaviour (Martin, 2006, p.262). In contrast however, there are numerous possible explanations for what mind-maps might legitimately do within a design task, including:

1. To develop lines of enquiry.
2. To scope a field of study.
3. To capture what the student already knows about the topic.
4. To break down and categorize complex words and phrases.
5. To make creative leaps.

Although students referred to their knowledge representations as "mind-maps", they are not Mind Maps™ as described by Buzan (2010). The students' diagrams did not follow the procedures advocated by Buzan (2010) in relation to Mind Maps™, or by Novak and Cañas (2006) in relation to concept maps. This project therefore analyses practices of knowledge representation as presented by undergraduate students rather than ideal examples from the literature.

The research was initially motivated by a wish to understand the reason *why* students engage with mind-mapping. A Grounded Theory, data first approach therefore seemed appropriate where concepts could emerge from the data itself. The question slowly turned

however, through the open coding stage, to questions about *what* kinds of knowledge were being used and the nature of the links made. Did these links resemble creative leaps or a more mundane filling in of the territory defined by the project brief?

2. Open coding stage

The open coding strategy follows Corbin and Strauss (2008, p.160) who describe a three-stage process, involving breaking "data into manageable pieces"; "interpreting those data"; and giving the pieces of data names that stand for the ideas they contain.

Coding schemes in the literature, are frequently based on interview transcripts (Charmaz 2014). These are essentially monomodal; using character strings to capture vocalisations stripped of intonation, physical gestures, and expressions. In contrast, the mind-maps which in part comprise the data for this project, are multimodal: involving multiple kinds of communicative resources. In the open coding phase, three different issues arose out of the dissimilarity between the coding of interview transcripts and mind-maps.

2.1 Units of analysis

The first difference involves the breaking down of data into units of analysis. In relation to interview transcripts, Charmaz (2014, p.127) lists the following: "Word-by-word, line-by-line, segment-by-segment, and incident-with-incident". This repertoire of units is not sufficient to engage with mind-maps as data. Meanings attributed to mind-maps are also mediated by such things as placement, and scale, and depend on more dynamic spatial relationships with other network elements. Figure 1a is a schematic version of the first mind-map analysed, this is abstracted further in Figure 1b. A range of different supplementary structures are defined below:

- There are individual *elements.*
- Elements are connected by *paths*.
- Two elements connected by a path make a *binary construction*.
- *Branches* are built out of one or more binary constructions.
- There is an element in the centre of the mind-map from which branches radiate, this is the *central node*.
- Paths can have a *direction,* for example moving from the centre to the periphery of the mind-map (indicated by arrows in the data).
- Binary constructions have an *inner element* closer to the centre of the mind-map and an *outer element* further from it.
- All of the elements at the same remove from the central node are referred to as being on the same *orbital*.
- All of the elements connected to one radial element are referred to as a *radial sub-network*.

- Elements not connected by a path to any other element are referred to as *radical elements*.
- *Links* are paths that link an element in one branch to an element in a different branch.

Figure 1a

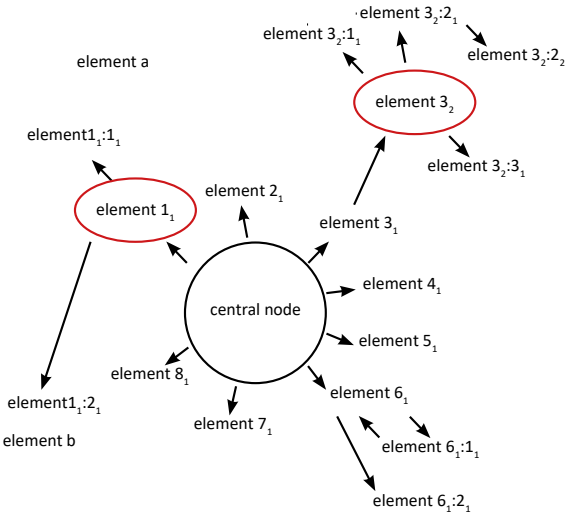

Figure1b

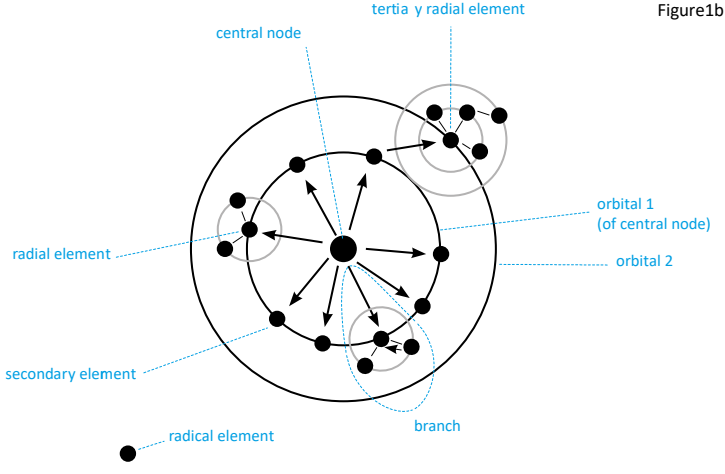

Figure 1.

In the open coding stage, it became apparent that patterns in the data are manifest in these additional units of analysis: different categories are often represented as branches for example. A focus emerged based on the links between elements. The binary construction provided the basic unit of analysis in the subsequent coding.

2.2 Reading paths

The second dissimilarity between data types arises from interview transcripts unfolding chronologically. This translates spatially into written text where each line reads from left to right, and each column from top to bottom. This same logic however does not apply to mind-maps which have any number of branches that can be read in any order.

2.3 Topics addressed by data

The topics explored in interviews are in many cases the focus of the researcher too. However, the topics explored by students in these mind-maps are not the primary focus, but rather, the relationships established by linking topics – whether the relationships are categorical or cause/effect for instance. It is at this more generalised level of analysis that we can begin to form inferences about the originality of the connections made between topics.

2.4 Coding Procedure

The coding procedure entailed starting at the central node and then moving out along one branch toward the periphery, this was then repeated for each branch. Branches included different kinds of links: chronological, categorical, etc. But these different connections frequently linked concepts directly related to the brief. This quality of the mind-maps – to remain categorically related to the central node – was emphasised when links were made to elements not circumscribed by the brief, and these appeared to be far fewer in number. This observation in the first round of coding led to the study focus, and two core concepts: *internal linking* and *cross-space mapping*.

3. Core categories: internal linking and cross-space mapping

As the first round of coding progressed it was noticeable that there were different levels of creativity in terms of the links made. One aspect of this concerned categorisation; if the outer-element was a sub-category of the inner-element this suggested a logical, straightforward association. If on the other hand, the outer-element belonged to a different category far removed from the inner-element, then this suggested a more creative association. The researchers were familiar with: conceptual blending theory (Fauconnier 1994; Fauconnier and Turner 2002), and frame semantics (Fillmore 2006), and recognised that these theories could provide useful conceptual tools for analysing the links between elements in mind-maps. Two concepts in particular were utilised: *mental spaces* and *frames*.

Mental spaces are constructed in the moment, as we think, for purposes of understanding. They are, "interconnected in working memory, can be modified dynamically as thought and discourse unfold" (Fauconnier and Turner, 2002, p.102). Many spaces can be active simultaneously enabling us to capture useful information from long-term memory and link them together in various ways.

The idea of a frame in Fillmore's theory is that words attain their meaning through the relationship they have to a structured conceptual setting. The often-cited example is the commercial event frame (Fillmore, 2006, p.378). Here a word such as "sell" is understood because of its relationship to other words such as "buy" and "seller" in the same conceptual setting.

Mental spaces can recruit elements from different frames, and whole spaces can be organised by a frame: whereby every element in the space is organised with reference to one conceptual setting.

The assumption in this article is that, within design culture, there is a familiar frame for a "brief" Although each brief is unique, there are recurring features in the way briefs are written. Analysis of the ISTD brief data yielded such recurring features (Figure 2a). Decisions about framing were not based on linguistic analysis, but on introspective reflection.

Each of these features – using the terminology of cognitive linguistics (Coulson 2001, p.19) – are *slots* that can be *filled* differently according to the brief concerned. Encountering a brief will prompt the construction of a mental space in which these slots are filled by elements. Though different elements can come from different conceptual frames they are still organised by the brief frame. We therefore think about them in terms of how they participate within the context of a brief.

An illustration is probably useful at this point. One generic feature of the brief frame listed in Figure 2a is *meanings to communicate* and such meanings can be tightly or loosely defined. The *Anniversaries* brief requires the communication of meanings about anniversaries and "Anniversaries" is therefore a filler for the slot *meanings to communicate.* Different students took this "anniversaries" filler and interpreted it at a more specific level. One, for example, focused on alcoholic spirits which introduces another frame (but this time not an organising frame): *making alcoholic spirits*. In this case, the alcoholic spirit is a cognac ready to drink on its 100th anniversary. This processing involves the construction of a mental space organised by the brief frame. The brief frame recruits those elements from the *making alcoholic spirits* frame that are relevant to the *Anniversaries* filler.

As the illustration below demonstrates there were different levels of generalisation amongst the codes emerging from the brief data. The mind-map data codes also showed different levels of generalisation, corresponding to those of the brief data (Figure 2b).

Figure 2a. Recurring codes from the brief data. All of these are potential fillers for the slot at level 3 of figure 2b.

Elements of brief frame
the product to be designed,
the audience or user,
the design problem,
the social and cultural context,
desired outcomes (deliverables),
technical and/or commercial constraints,
meanings to communicate (propositions),
tone of voice

Figure 2b. Hierarchy of different levels of frame components.

Level	Frame component	Potential instantiations of frame component	Level of generalisation
1	Frame:	Brief	High
2	Sub-frame of brief frame:	ISTD Anniversaries Brief	
3	Element of brief frame (slot): -part of frame	For example, meanings to communicate	
4	Type of meaning to communicate (filler): -part of sub-frame	For example, anniversary	
5 and below	Specific meaning to communicate: -student's response to Anniversaries Brief	For example, 100 year old cognac	Low

ISTD Brief	The 'potential meanings to communicate' element of the brief frame
Anniversaries	Anniversary, plants ('roots' used metaphorically to suggest the start of something), cyclical nature of the universe, typography.
Writing women into history	Recognising achievement, fields of endeavour, history, sexual equality, typography.
Mark my words	Abundance of language, language accretion, word history (including etymology), typography.
Food for thought	Analysing societies, distribution of dishes, history, food preparation, representation, typography.

Figure 2c. Different types of meaning to communicate as indicated by the ISTD briefs. All of these are potential fillers for the slot at level 4 of figure 2b.

Figure 2.

All of the codes in Figure 2a are potential fillers for the level 3 slot "Elements of the brief frame" in Figure 2b. The codes from the brief data related to level 4 of Figure 2b (the type of meaning to communicate) are listed in Figure 2c.

This conceptual framework of mental spaces, and frames, is used to distinguish between links that stay within the territory delineated by the brief, and those that connect to other outside elements. It is questionable as to whether it is desirable to be completely confined to the space delineated by a brief. While the brief's aims, and specifications cannot be ignored, designers often use other means such as metaphorical expressions to communicate which can involve two organising frames. Within mind-mapping this can be indicated by including two central nodes in the mind-map and by making links between these two networks.

The importance of making links to different domains is recognised by Novak and Cañas (2008) in relation to concept maps, and in "double-scope networks" described by conceptual blending theory (Fauconnier and Turner, 2002, p.340).

The idea of relating concepts from two separate and distinct domains unites the concept of *cross-space mapping* – that emerged in this study- – with: *transfer recall (*Guilford, 1967, p.214)*, bisociation* (Koestler, 1964, p.35) and *cross-domain transfer* (Pereira, 2007, p.3), described in theories of creativity. These are all forms of what Guilford (1967) termed *divergent production*. Furthermore, according to Pereira (2007, p.29) *convergent production* is also linked to creativity, if this is understood as the "creation of a *novel* and *useful* product" (emphasis in the original). Here, divergent processes provide novelty while convergent processes provide usefulness.

We should not be too dismissive of working entirely with the conceptual elements circumscribed by the brief. As we have said this mental space will contain elements from different conceptual domains and it is possible to make metaphorical or counterfactual links between these also. In mind-maps this can be represented by making links between the different branches of the mind-map.

Just as c*ross-space mapping* loosely corresponds to aspects of divergent production, *internal linking* – which concerns associations made within one mental space – suggests convergent production. The twin aspects of convergent and divergent production that are a prominent feature of theories of creativity are therefore supported by the codes emerging from the data.

4. Second stage coding

The central nodes in all the mind-map data refer to the ISTD briefs, although some more explicitly than others. The assumption is that the central node prompts for the construction of a mental space, thereby evoking an organising brief frame. Those elements of the mind-maps that form part of this mental space should therefore be coded as examples of internal linking; those on the other hand that fall outside of this mental space are candidates for cross-space mapping. This coding stage employed a two-track strategy.

This strategy involved working progressively outward through the binary constructions in each branch. If the inner and outer elements of each binary construction were deemed to be 1) in the same frame, and 2) related to the organising brief frame evoked by each brief; then the link between these elements was recorded as an internal link. If, on the other hand, one of these conditions was not met then this raised the possibility that the link was a cross-space mapping, requiring further scrutiny of the binary construction to determine which frames were involved.

At this point it is probably helpful to provide examples of different scenarios, emerging from the data.

Table 1. Internal linking using a single conceptual domain. ISTD brief, Anniversaries.

Elements from the data
Central node: "Anniversary"
Element 1_1: "Culture"
Element 1_2: "Thanksgiving"

Here the topic "anniversary" is provided by the brief's title. Of all the yearly events that take place, some are "cultural" and within those is a particular anniversary "thanksgiving". This involves a movement from the generic to the more specific within one frame – anniversary.

Table 2. Internal linking using two conceptual domains. ISTD brief, Writing women into history.

Elements from the data
Central node: "Writing women into history"
Element 1_1: "Hidden figures"
Element 1_2: "NASA"

In this example NASA is not an established sub-category of "hidden figures" in the same way that "thanksgiving" is in relation to "culture". The label "hidden figures" is part of the "recognising achievement" frame while "NASA" belongs to the "fields of endeavour" frame (Figure 2c). Consequently, this construction requires more work from the reader to determine which part of the "NASA" frame relates to the frame "hidden figures" (workers in NASA that are "hidden" from history). Also, we are not interested in all hidden figures, only those that are women (a focus handed down from the central node). This branch therefore results in a similar movement from the generic to the specific as in example 1 but one that requires more processing since two frames are more clearly involved. However, since both frames are part of the same organising frame evoked by the brief, this is still an example of internal linking, rather than cross-space mapping.

Table 3. Cross-space mapping using two conceptual domains (two organising frames – metaphorical). ISTD brief, Mark my Words.

Central node: "C word" and typography	
Branch 1	**Branch 2**
Element 1_1: "Sound	Element 2_1: "Punctuation -Bullets + Ammunition"
Element 1_2: "Short quick" ⟶	Element 2_2: "Gun shot"

In this example two elements are linked suggesting the metaphor expletive is gun shot. The "short quick" sound of the "c word" linking here to "gun-shot". This involves two different organising frames: that of words and typography (part of the brief frame), and the shooting of guns (external to the brief's organising frame). Interestingly the recruitment of this second frame seems to have happened in Element 2_1 where an association is made between a bullet point (a typographic glyph) and bullets/ammunition. The implicatures of this metaphor would seem to provide useful communicative potential so that swear words become *wounding* and are *fired off* in a hostile act.

Table 4. Cross-space mapping using two conceptual domains (two organising frames – counterfactual). ISTD brief, Mark my Words.

Elements from the data
Central node: "what if"
Element 1: "nice had a smell"

This central node here makes an indirect reference to an ISTD brief; the connection is only clear once the link is made between "what if" and "nice had a smell" since "nice" is explored in relation to the "Mark My Words" brief. The cognitive work involved in this "what if" processing is impressive. "Nice" is of course a word used to *describe* physical things or events and is therefore part of the language frame. But the "what if" – "nice had a smell" construction forces us to think of "nice" not as a word but as part of another frame, one of physical things. When combined with this second frame "nice" becomes itself an *object* that is available for scrutiny by our sensory organs - it has a smell. This objectified imagined manifestation of "nice" moves it outside of the language related elements listed in Figure 2c. It is an example of a counterfactual construction.

All of the data were coded on the same basis as these examples and were assessed as being a case of internal linking or cross-space mapping using the criteria discussed above. Codes were collected and analysed using NVivo 12 software.

5. Results

The sample consists of fifteen students who entered the 2018 ISTD Student Assessment Scheme. Of these entrants, ten produced mind-maps as part of their submissions and nine of these participated in the study. There were fourteen different mind-maps produced by these nine students, all of which were coded and analysed.

Database queries of the codes yielded 301 links that were assessed as being internal linking, as opposed to 23 links being assessed as cross-space mapping. Of the 23 cross-space links, twelve came from a single mind-map that labelled the central node "what-if". The other 11 cross-space mappings were distributed across two other mind-maps; of those one had a

central node providing a level 3 (see Figure 2b) reference to the brief, this provided nine cross-space mappings. The remaining one was a response to the *Anniversaries* brief and the central node was labelled “whiskey + distilleries + spirits”, this mind-map yielded two cross-space mappings. Overall there were 16 links which were either illegible or so vague or ambiguous that it was decided that their inclusion in the study would introduce unreliability.

With regard to examples of counterfactual thinking, there were two examples of counterfactual thinking as internal linking, and 12 cases in which it occurred across spaces.

6. Discussion

This study began with a degree of scepticism as to the efficacy of mind-mapping as a tool for idea generation. The coding results at first suggested that this scepticism was not misplaced, with comparatively few cross-space mappings in relation to the number of internal links established. The nature of the internal links is often rational, relevant but somewhat unsurprising, consisting – as many do – of categorical links stepping down from superordinate classes, to subordinate classes. Generally, the mind-maps tend not, to provide links to more distant conceptual domains suggestive of divergent thinking.

Yet there was one exception that generated twelve out of the total of 25 cross-space links. What differentiated this mind-map from the others was the placement of “what if” in the central node of the mind-map – rather than a more direct link to a brief. The “what if [x was …?]” statement prompted counterfactual scenarios to be imagined that often included concepts from domains distant from those organised by the brief in question. Further possibilities could be achieved by placing other questions at the centre of mind-maps “x as …?”, or “x is …?” for example, and this could be a source for further study.

The second most productive mind-map (nine cross-space mappings) has “c**t & typography” in its central node. This expression itself involves two conceptual domains; that of typography and the body. This may explain why the mind-map constructed around this node was so prolific in terms of cross-space mappings.

A further reflection on the mind-maps concerns the way that the central node potentially frames enquiry. By starting with a superordinate class in the central node there is the question of whether this primes the creator of the mind-map to think of other categories, rather than say attributes or abstract qualities. For example, in one of the mind-maps, “Anniversaries” is placed in the central node which links to another radial element “Cyclical nature of the universe”. This might have triggered an exploration of the abstract quality of cycles, building associations with domains not directly related to anniversaries such as bicycles, vinyl records, and so forth. Mapping a single revolution of a record to the year of a life, could result in surprising outcomes that highlight different aspects of anniversaries. For example, a revolution on the periphery of a record is longer than a revolution closer to the centre; which is reflective of the experience of time passing more quickly as we get older.

However, it would seem that the line of reasoning set up by the superordinate category of "anniversaries" led not to the abstract quality of *cycles* but to the category of *astronomical cycles* – which is a less creative leap, since the annual cycle of the Earth around the Sun links directly to the concept of "anniversary". The question arises therefore as to whether mind-mapping constrained thinking in this case.

Pereira's observation above is worth consideration here, where he notes that a creative product should be both novel and useful, and that these attributes arise from divergent and convergent production respectively. If "usefulness" in this context is translatable as "relevance", it appears that most of the internal links made in these mind-maps have quite a high degree of relevance to the idea placed within the central node. At first glance, the cross-space mappings perhaps less so. But according to Schilperoord's (2018: 14) summation of current accounts of metaphorical meaning, the incongruity resulting from the juxtaposition of "two objects stemming from disparate domains" is an important prompt for metaphorical association. It induces the viewer/reader to do cognitive work that finds the connection between two seemingly disparate things. The importance of these cross-space mappings should not therefore be undervalued.

If there are priming effects at work in mind-maps then this might account for the disproportionate number of internal links reported in the results, since one element in the mind-map would prime the creator of the mind-map to find another element closely associated with it in memory – and this suggests convergent production. Consequently, whatever appears in the central node would frame and to some extent determine, what appears in the branches that radiate from it. It could be argued that this is precisely the point of mind-maps. But if this is the case, is there less opportunity for the divergent, cross-space mapping of which the brain is capable? It is conceivable that this potential is even suppressed, in the creation of mind-maps.

From the admittedly small number of mind-maps analysed in this article, it would seem one way to open up mind-mapping to divergent, cross-space mapping is to put questions such as "what if x was …" in the central node of the mind-map rather than simply the name of a category.

Abstract | This paper analytically connects the theme of collaboration, with an emphasis on the historical production structure of the Emilia-Romagna region and the increasing spread of cooperative platforms. This analysis gives rise to reflections on the characteristics and processes that distinguish the object systems from research. The multitude of instruments that appear in the research underlines the partial coverage of the area of the specific project, which is characterized by the complex process that relates raw materials to the logistics of distribution by the systems and the companies based on cooperative platforms. Within this research area, this contribution aims to elaborate some guidelines for the development of these systems on the subject of welfare, the relationship between collaborative and cooperative forms and the future application of artificial intelligence in the assessment processes that are crucial for the design of innovative models of cooperative platforms for processes of product creation and management.

KEYWORDS | COOPERATIVE PLATFORM, PLATFORM FOR DESIGN, DESIGN AND TERRITORY, DIGITAL MANUFACTURING, CREATIVE COMMUNITY

1. The state of the art of the cooperative system

The Italian context, particularly that of the Emilia-Romagna region, was characterized by different forms of consumption and production of goods and services that are jointly managed. In the course of time these development processes of the work have strongly shaped the area, which has always shown a particular preference for viewing these aspects as typical elements of a regional system, both socially and culturally. They promote socio-cultural growth through models in which the customer is at the center of the innovation process, and they themselves become actors of change and active figures in the creation of new forms as well as entrepreneurial and social processes (Villari, 2018). These are changes in goods, services and processes to meet the need for intelligent growth that is open to social responsibility and innovation, creating new market modalities and new relationships within the participants (Celaschi, 2016).

One modality is the collaborative economy, a model that redefines and updates the relationship between market, product / service, production processes and consumers while activating new avenues of production and consumption. A social and economic approach that is heading towards a dynamic of collaboration and co-creation between subjects and aims to create solid relationships between the offline and online attitudes. Vincenzo Cristallo (2018, p. 37) highlights how three actions emerge from the collaborative economy: the "collaborative consumption", the "collaborative market" and the "value of experience". The first activates three elements: the role of the community, mobile collaboration, and inexhaustible resources. The second relates to resource sharing and the third shows how the value of products and services is related to finding an experience. The goal is no longer the use and ownership, but the empirical value that enables access to this asset.

While it is clear that the phenomenon of the collaborative economy still has very broad and changing boundaries due to its growing diffusion and heterogeneity, the main features and differences within the most common collaborative models are examined. Starting with governance, this can either be centralized or widespread, geared towards profit or pursuing a social purpose, more capitalist with centralized control to more democratic and horizontal (Battistoni et al., 2015, p. 23; Kostakis & Bauwens, 2014)) it shows that the forms in which these models are implemented are mainly four: collaborative consumption, collaborative production, collaborative learning, and collaborative financing (Stokes et al., 2014). In these contexts, the element that most unites the different forms is the peer-to-peer dynamic and the contribution of digital technologies as a connecting tool between users.

As we proceed to analyze each of the models, some of them appear to use collaborative and exchange practices to respond to the material and social needs of the community. An approach that turns to some principles of the cooperative model to create alternative businesses to capitalist companies that combine the associative dimension with the entrepreneurial.

Historically, the cooperative model starts with the beginning of the industrial revolution and the first models emerged in Europe in the mid-19th century, focusing on consumption, work, agriculture and credit. An interesting case study is that of the labor cooperative, which was born in Paris in 1831. This was the first cooperative association of carpenters, which was later followed by others related to goldsmiths, furniture makers, bakers, stonemasons and all interesting forms of community experimentation (Zamagni & Zamagni, 2008). The members were also the workers themselves, and all equally enjoyed the principles of reciprocity, the founding feature of cooperatives, aimed to meet common economic, cultural and social needs. Italy was no stranger to these processes of job innovation and stood out for the development of models of cooperation in different areas, from consumption to production, from agriculture to credit, up to the social cooperative model.

The first evidence found from the sources is in Turin, 1854, with the first consumer cooperative, and always in the same period,1856, in Altare near Savona was registered the first cooperative production dedicated to glass art. The cultural and associative model was already existent in Italy, as it was in Europe from the mid-18 century thanks to the Mutual Relief Societies between workers, born to replace corporate structures, which for their formula dedicated to community support and mutuality were inspiration for the creation of Cooperatives (Zamagni & Zamagni, 2008, p.73).

By its definition, a "cooperative is an autonomous association of people who have come together voluntarily to meet common economic, social and cultural aspirations and needs through the creation of a common and democratically controlled corporation," as in the Declaration of Cooperative Identity displayed in Manchester in 1995. It is also defined by the following principles: free and voluntary membership, democratic control by its members, economic participation of its members, autonomy and independence, education, training and information, cooperation between cooperatives and interest in the community. Over time, market changes have contributed to the development of cooperative forms and the introduction of new legislation, which have also led to the creation of new forms of governance.

In this regard, the emphasis in determining some of the parameters in the tables below has been rather on the prevailing cooperative model of reciprocity, which keeps the intrinsic principles of the cooperative more intact. In addition, the fields of production and labor were further examined, a sector which, by its conformation, bases its actions on a continuous synergistic dialogue between the different actors in the supply chain and guarantees the identity values of what they produce. A distinguishing feature of cooperative production is the figure of the worker member who "pursues the good of the cooperative by lowering personal expectations of mutual exchange". (Legacoop, 2010, p. 67). If we compare this model with that of the collaborative production economy, we find connections that highlight how both are based on the idea of a common project of the community involved in it. It is plausible to argue that some rationale, such as equipment sharing and the collaborative manufacturing spirit, are common, especially when it comes to collaborative

manufacturing which is intended in the context of open manufacturing (Battistoni et al., 2015, p. 50). In Emilia-Romagna in particular, an analysis of the territory's entrepreneurial systems shows that the cooperative model is an entrepreneurial method of collaboration that is still relevant and has a strong connotation with social innovation processes. The UnionCamere dataset for 2018 confirms this with 80,765 cooperative companies on Italian territory, of which 5,006 are articulated in the Emilia-Romagna region and employing 12.5% of national employment related to cooperatives (Rapporto sulla Cooperazione, 2019, pp. 55-56).

Basing on the literature as early as the twentieth century, the development of the new cooperative business models of Emilia-Romagna distinguish itself at national level thanks to the historical ability of the regional territory to create a system, to its geographical conformation rich in small-medium enterprises well integrated in the productive regional setting, and to its aptitude to combine political culture, integration between public and private, entrepreneurial culture and social integration in a virtuous formula. All elements that in the second half of the twentieth century defined the "Emilian Model" (Menzani, 2007), which was one of the driving forces behind the transformations of the territorial cooperative model which differed from the others precisely because of one of its peculiarities: the social integration. Its widespread diffusion in the region, already after the war, allowed the regional economy to consolidate and renew itself, creating close ties with community and institutions.

Within this territorial ecosystem, the development of production and labor cooperatives is interesting as they find their best locations within the production districts and new resources both in the know-how of the local artisanal production tradition and in the training of high-level skilled professional (Menzani, 2007). The manufacturing cooperation was able to take advantage of the large training capacity and capillarity that had settled in the region, guaranteeing a high level of skills that contributed to the success of the manufacturing cooperatives in the ceramic, shoe, foundry and mechanical systems market.

The cooperative model is particularly interesting because it is still relevant today and, according to its principles, corresponds to the objectives of the European Community in matters of social innovation and inclusion as well as the development of new socio-economic sustainable models. A model that, when applied to the online world and contaminated with new trends in open design, can be an alternative approach and solution to the complex needs of the current and future market.

To understand this phenomenon and develop design-oriented processes, the different systems and types of contemporary entrepreneurship in the market are examined.

2. Contemporary digital models of collaboration and cooperation

The development and diffusion of ICT infrastructures, the reduction of transaction costs, the change of buying habits from a “own” to a “share” approach and the disappearance of the clear distinction between consumers and producers (prosumerism) are some of the conditions that have spread the sharing economy. There are misunderstandings and contradictions where some of the patterns of consumption that are commonly grouped under the term “sharing economy” do not reflect their principles. This can often be attributed to the habit of extending the metaphorical meaning of neologisms associated with the digital world to related concepts, tools, and practices. This phenomenon tends to dilute the specificity of the terms and introduce a number of umbrella terms that create ambiguity and semantic confusion (Ciracì, 2013). According to Giana M. Eckhardt and Fleura Bardhi (2015) the term “sharing economy” is not used properly on platforms such as Uber[1] and Air B & B[2]. In fact, the exchange of goods, services and information based on the Peer2Peer model is a phenomenon that occurs between individuals without any currency exchange taking place, but which is driven by a mutual and supportive approach. When there is a market broker between users who do not know each other, an economic exchange relationship is established by defining an access economy rather than a sharing model. This dynamic has a direct impact on how users of the platform use the service. It favors the return of economic value over social value and makes us wonder to what extent the peer relationship is perceived as an added value or a compromise to access the service.

The platforms that offer this type of service do not own the resources, nor are they responsible for the actions of the individuals. For example, Uber does not own the vehicles and has no obligations to any of the operators involved in providing the service. In the food delivery sector in particular, the use of bikers as the only resource without protection and recognition of their status as employees has a significant impact on the economic competitive dynamics of the dominant service companies. There are alarming social implications in this regard, and in response to these models, a debate has emerged in recent years about the role of platform cooperatism as a fairer and more sustainable economic model (Rifkin, 2014; Scholz, 2015).

The cooperative platforms are part of a panorama of typologically different online platforms on which the differences in the processes guide the structure and implementation of the actions they generate. Cooperative platforms are identified with four main characteristics (Scholtz, 2019): ownership that is extended to the members of the platform; democratic management of the same when a member's vote is worth one; the co-design processes that

[1] Uber, https://www.uber.com
[2] AirB&B, https://www.airbnb.com

guide the development of the platform; the obligation to support an open source development of its organizational instruments.

These features underline the similarity and diversity of the platforms that result from the collaborative economy. Two platforms enabling a transportation service could serve as examples, with the first, Uber, gathering self-employed workers under the same brand and app and asking for a percentage to pay for the service. The second platform, Eva[3], guarantees the same service, but structures the internal processes according to the scheme of the cooperative platforms. This choice, based on blockchain mechanisms, allows the members, through the development of the common platform, to generate a surplus of profit intended to transparently redistribute the value on the territory. The cooperative model generally guarantees higher profit margins for members, their participation in company decisions through voting, and better protection by hiding the verification data from the application interface.

The models are similar from the user's perspective, but different from the employee's perspective.

Cooperative platforms interweave multiple relationship models between members and the market by defining competitive, collaborative, algorithm-based forms with multiple stakeholders. For example, when using the American UP & GO[4] platform, the user does not have the option of selecting the operator responsible for cleaning based on the personal profiles of workers whose ranking or public rating does not exist. The user relies on the evaluation process carried out by the cooperative when selecting staff. This decision was guided in particular by tests carried out by the platform and studies that suggest that personal profiles could lead to harassment (Scholz, 2019).

Some models of cooperative platforms are characterized by the fact that several participants with different roles are accepted as members. These cooperatives are defined as multi-stakeholders and consider the involvement of workers and producers as members of the cooperative. For example, the Resonate[5] model expects content producers and users of the service to have the right to vote on the decisions that determine the development of the platform. In addition, the profits are shared among all stakeholders, who can choose to withdraw them as cash or use them as credit towards using the music streaming service on which the platform is based.

The mapping of active cooperative platforms is constantly updated (#PlatformCoop Directory - The Internet of Ownership, n.d.). In the past year, Scholtz (2019) divided the platform types into five categories:

[3] Eva, https://eva.coop
[4] UP&GO, https://www.upandgo.coop
[5] Resonate, https://resonate.is/why-were-a-cooperative/

- The production cooperatives are constructed as spaces where the members who create the content independently benefit from a single diffusion vehicle (i.e., Stocksy[6]), or as aggregation places of professionals developing joint projects (i.e., Enspiral[7]).
- Data platform cooperatives deal with user-driven social media;
- Cooperative platforms are based on blockchain protocols (i.e. Eva);
- Labor cooperatives aimed at providing services to their members (i.e. Up & Go);
- Collaboration platforms for common tasks aimed at bringing together non-group professional groups and helping them manage work activities. (i.e. Docservizi[8], Smart-it[9])

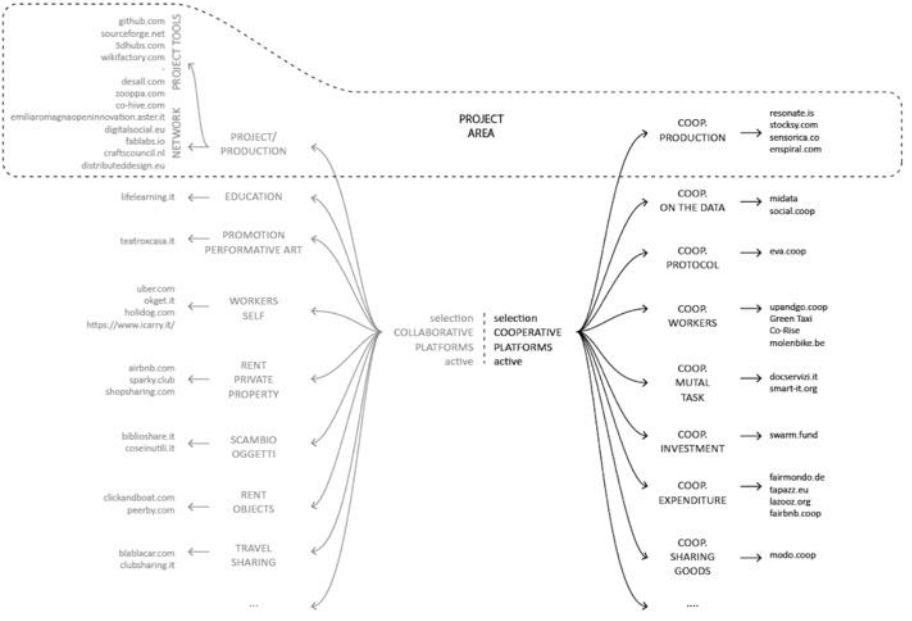

Figure 1. Collaborative and cooperative platforms.

Figure 1 shows how it is possible to insert other categories in relation to those already identified, with an emphasis on different aspects. Similar difficulties with categorization arise in connection with collaborative platforms, which, as mentioned above, often have a similar

user interface on the user side, but with specific internal procedures that sanction a profound ideological divergence.

The diagram shows how both branches represent platforms that are mapped to fields related to the project area. On the collaborative platform side, it can be stated that this area is essentially represented by two macro-categories: instrument supply platforms and network platforms. The former offers designers digital tools for their work like GitHub[10]; The latter connect the stakeholders of the design processes (i.e. co-hive[11]) and in some cases collect real orders that have been established between the company and the platform and which are then managed by the designers through working groups (Zooppa[12]) or competitions (Desall[13]).

By focusing the analysis of collaborative platforms on issues related to product design, it is found that the role of the platform is mainly limited to distributing the goods. The collaborative development processes seem to be mainly hosted on digital platforms that provide tools for coordinating workgroups like GitHub and Wikifactory[14]. Although these platforms are based on the active involvement of the participants in the development process, they do not contribute to build long-term collaborations, but create collaborations that are linked to individual projects. In this sense, the platform is only used as a collaborative tool and does not represent a common basis for the exchange of values and purposes, an element that characterizes cooperatives.

In order to be able to deepen the processes of the case studies of cooperative model platforms that intervene in the area of design, a descriptive matrix (Fig. 2) of internal processes was used where the case studies are analyzed through the characteristic coming from both the traditional cooperative model and the digital cooperative platforms. While two case studies declare themselves in their statute as cooperative platforms, the remaining take alternative forms in which the social aspect towards the members and the reinvestment of profits in the same area can be registered.

3. Discussion

The policies implemented by the recent regional councils of Emilia-Romagna have, amongst their objectives, the regeneration and development of employment, in line with the demands of the European Community for a new social cohesion. Attention to the development of new business methods through the cooperative entrepreneurial system is seen as a tool for sustainable and strategic growth of the territory. The goal is to develop new forms in areas other than traditional, including through the creation of start-ups and measures that contribute to cross-sectoral contamination within the supply chains (Alberani, A., et al., 2018). Among the initiatives to support the regional development lines, mention should be made of the Social Hackathon[15], which was organized in Piacenza in 2017 by Confcooperative, a collective hacking action based on the open innovation model of Henry

[15] Social Hackathon, La prima maratona di Solution Making a Piacenza, http://www.confcooperativepiacenza.it/social-hackathon/

Chesbrough (2003) but more cooperative and the Coopstartup Bologna[16], a new co-op development program that offers winners an annual call, guide, and acceleration process.

As mentioned earlier, this research focuses on the interventions and development of digital and immaterial forms and tools in the specific area of the project. In the selection of the analyzed case studies there is a single example that does not belong to this classification: the Sensorica[17] community, whose goal is the development of open source hardware by its members. Together with the Enspiral project, this platform does not define itself as purely cooperative, but actually fulfills many of the requirements identified by Scholtz. The two platforms offer digital rooms in which working groups are created on specific project priorities. In the case studies analyzed, it is interesting to highlight the Stocksy and Resonate platforms, which are characterized by offering members a collaborative / competitive model that is integrated into associative management and allows them to participate in the decision-making processes of development and active cooperation in the EU to participate in the management and design of the platform. Their front-end model is configured as a wider audience digital space where preferred content can be purchased. The basis of these two online platforms is the clear desire to protect the copyright of individuals and to guarantee their members fair compensation. Transparency and clarity in managing retained earnings through both platforms is one of the most important added value values that enable it to attract members from competitors.

Taking into account the specific area of product design where there are currently no examples of structured collaborative platforms, a significant contribution to their development, particularly in the production and distribution phases, could come from the contexts that have evolved on the EU basis for open and shared philosophies such as Fablabs, Maker and Hacker Spaces.

In fact, the digitization of the design phase and the spread of the enabling technologies of Industry 4.0 offer the opportunity to imagine innovative and flexible production and sales processes. One analyzed case study based on these issues is the Distributed Design Market Platform project[18], which is funded by the European Union through the Creative Europe fund. This project promotes platforms and tools that support designers and makers not only in the design, but also in the manufacture and marketing of their products and support processes that are based on the exclusive handling of data and widespread production.

By digitizing the project, digital collaboration platforms can be used to simplify co-design processes. Many of these online tools were developed to facilitate software development, particularly in the open source area. They offer hosting services, version control, bug tracking systems, feature requirements, task management and wikis such as GitHub and

[16] Coopstartup Bologna, https://bologna.coopstartup.it

[17] Sensorica, https://www.sensorica.co

[18] Distributed Design Marekt Platform, https://distributeddesign.eu/about/

SurceForge[19].

Based on these models, additional platforms for the co-design of physical products were developed. On these platforms, the project management and tracking tools are flanked and integrated by tools that have been specially developed for product design, e.g. B. the online visualization of 3D models and the creation of a dynamic parts list that can be shared with external suppliers and manufacturers. Examples are Wikifactory, GrabCAD[20] and Thingiverse[21]. Although the tools described are not hosted on cooperative platforms, they represent technological solutions that correspond to the characteristics of cooperative models.

In addition to the technical support tools for design, there is one area of particular interest for design, namely the collaborative platforms for common tasks.

The analysis provided in this discussion summary shows that application models of the collaborative system cannot really be used to create platforms dedicated to the context of design. Hence, it seems necessary to create design scenarios that lead to the development of guidelines to ensure true compliance of these tools with the cooperative model.

4. Guidelines for design and productive cooperative platforms

The findings that emerge from this study of the cooperativism of Emilia-Romagna and the cooperative platforms in a broader and more general context, frame possible development of the cooperative platforms towards complex production realities characterized by the participation of several participants in the production processes.

Thanks to these developments, new cooperative models should take into account some aspects that deal with the field of production through digital mediation. In particular, three macro-themes emerge: the importance of the welfare system, the contrast between a competitive and collaborative approach, and the assessment processes that need to be developed to improve member evaluation.

One approach highlighted in the platform case studies is to improve community welfare. On the one hand, there are platforms to support freelancers by inserting them into networks and assisting them with the tax and organizational administration of customers. On the other hand, a regional system that has always been recognized for having pursued the aspect of social integration within regional and economic policy and which is still moving in this direction today through communal welfare projects involving institutions, citizens and communities work together to create systems that contribute to the economy of caring for

[19] SourceForge, https://sourceforge.net
[20] GrabCAD, https://grabcad.com
[21] Thingiverse, https://www.thingiverse.com

the common good (Symbola, 2018). Social relationships and quality of services are a combination that leads to a better quality of work and a more sustainable and conscious production, which is now also demanded by the end consumer.

The welfare instrument can also be inserted between the innovation and systems practices of cooperative platforms for both production and design in order to improve relationships in the network and in labor management.

From the analysis of the case studies it appears that the platforms that offer digital products are configured on the user side as places where one member's content and not the other's can be purchased, which of course creates a competitive aspect among members that is not possible is easy to evaluate.

Due to the number of participants involved in the process, the content distributed by these platforms is less complex than for material products, in which machines are used, raw materials are handled, stored and sold.

The cooperative model of Emilia-Romagna, closely linked to specific productions and combined with the concept of a cooperative platform, proposes what is necessary for the creation of aggregative digital places of the manufacturing vocation.

The cooperative networking of partners in synergy effects on a productive goal and not in the internal competition for the results could more closely adhere to the digital platform model intended for specific productions. Collaborative processes, managed through processes of transparency and equality between members, can lead to higher quality in the development of end products by improving the productivity of the platform.

Finally, the paper focuses on the processes of evaluating the work of shareholders. Comparison systems based on algorithms and artificial intelligence can lead to possible tools for managing the assignment of work activities to the platform operators. As in the Up & Go example above, the user relies on the selection criteria used by the platform and adapts to the system. At this level of interaction between the parties, the question arises of how fair and transparent the rules on which these algorithms are based are. Indeed, making machine learning and artificial intelligence (AI) mechanisms understandable is gaining political value in terms of equity, reliability, and transparency as these systems are increasingly used in managing sensitive data and decisions (Matsakis, 2018).

AI can also be used to create value for users within the platforms. Little by little, platforms are emerging that integrate processes based on neural networks to improve profiling systems. For example, Open Maker Digital Social Platform uses an AI-based value system to search for innovators on social channels, connect them based on common interests, and provide metrics to assess members' social impact and innovation. The application scenarios of technologies based on blockchain systems that help manage the transparency of the assessment processes are just a few of them that could lead to innovations in these decision-making tools in a short period of time. The crucial hub of the relationship system between

members is a fundamental element that will determine the future of collaborative platforms. The logic of the processes commanded on performance data must leave room for really comparable quality indicators.

Michele Zannoni is Associate Professor at the Department of Architecture of the Alma Mater Studiorum Università di Bologna, where he is a member of the Advanced Design Unit. His publications include articles in SCIRES-IT journal and Material Design Journal. He is the author of the book Progetto e Interazione (Quodlibet, 2018). From the year 2000, he taught at the IUAV of Venice, the Polytechnic of Milan and the University of the Republic of San Marino where he was the director of the master's degree in Design. Since 1997 he has worked as interaction and visual designer in several design agencies: at Studio Altermedia, at Studio Visuale form 2008 and at last in BDS Design from 2014. In these companies he has worked on national and international projects, winning international awards in the fields of multimedia and interface design and in particular, he has collaborated since 2009 with the Technogym design center, and has designed many of the company's user interfaces.

Giorgio Dall'Osso. Designer, his research focus is the relationship between body and technology. Since 2016 he is a member of the Advanced Design Unit, the design research group of the Architecture Department of the University of Bologna. His research interests focus on basic design and behaviour design.

Alberto Calleo. Graduated in Building Engineering at the University of Bologna. He has been Tutor and Adjunct Professor for the Degree and Master Degree Course in Industrial Design at the same University where he now collaborates with the Advanced Design Unit. His specific area of interest are product design and architecture with a focus on of innovative digital technology.

Laura Succini. Architect with experience in strategic design for the territories, with focus on the development of the productive culture heritage and the relationship between the territory, local manufacturing and creativity. She has been co-curator of Open Design Italia for many years. At the moment she is a PhD student and her research focus on the development of collaborative innovation processes for the valorization of tangible and intangible heritage within territories and the activation of new sustainable local economic and cultural models. Since 2018 she is a member of the Advanced Design Unit, the design research group of the Architecture Department of the University of Bologna.

Playing for change: designing a board game for the circular economy

Tom Cockeram [a], Jessica Clare Robins *[b], Emmanuel Tsekleves [b], Leon Cruickshank [b]

[a] Manchester Metropolitan University, UK
[b] Lancaster University, UK
*j.robins@lancaster.ac.uk

Abstract | There is a lack of public engagement in sustainability initiatives such as the circular economy (CE). This can be attributed to an absence of understanding and promotion of this new way of living and consuming. This lack of engagement is hindering the implementation of the CE. This paper aims to address this through an exploration of the role of games in explaining difficult concepts. There will be a particular focus on board games as tools for exploring aspects of sustainability, as they allow for a more discursive experience with other players and are a simple way to relate complex ideas. The paper will then detail the design and development of a serious board game *Circul8*. Designed by the authors to encourage engagement with complex systems, it aims to introduce ideas of the CE to the general public. The paper will explore the methodology of game creation and detail initial gameplay results.

KEYWORDS | GAME DESIGN, CIRCULAR ECONOMY, PLAY THEORY, LEARNING THROUGH PLAY, RAPID PROTOTYPING

1. Introduction

There is an urgent need to engage the public in the circular economy as part of the fight against climate change. The basic principles of the circular economy are simple enough; “design out waste and pollution; keep products and materials in use; regenerate natural systems” (Ellen MacArthur Foundation, 2017). However, understanding how these principles can work in reality is more complicated and there is a risk that people will switch off if they don’t understand. Research into the circular economy has revealed that public engagement is one of the most difficult aspects of circular economy implementation (Kirchherr et al., 2018). This paper will firstly explore the potential of the circular economy as a model to tackle some areas of the climate crisis, and the barriers around public engagement that are hindering its implementation. The paper will then go on to explore the potential of games to engage the public with complex ideas through a simple system, with a particular focus on board games. Finally, the paper will detail the designing of a serious board game, Circul8, by the authors, that will be used to engage audiences with circular economy ideas and provoke discussion around it.

2. Circular economy

The circular economy is gaining traction as an idea across business, governments and academia. It is seen as one of the ways to tackle the climate crisis by radically changing the way businesses operate and people consume (Ellen MacArthur Foundation, 2013; Ghisellini et al., 2016; Kirchherr et al., 2017; Mathews & Tan, 2016). The fundamental idea behind the circular economy is to move us from a linear economy of ‘take-make-dispose’ to one where resources are in constant use for their full usable life. There has been a variety of definitions for circular economy, ranging from product reuse and advanced recycling to eco-design and sustainable consumption (Gallaud & Laperche, 2016). Kirchherr, Reike and Hekkert (2017) analyse 144 definitions of the circular economy in order to consolidate and create transparency around current understandings. Their research concludes to define circular economy as “an economic system that replaces the ‘end-of-life’ concept with reducing, alternatively reusing, recycling and recovering materials in production/distribution and consumption processes.” (2017, p. 229). The Ellen MacArthur Foundation (2013) adds that systems should be restorative by design, focusing on nature-based systems as well as technical ones. The circular economy cycles are demonstrated by Figure 1, known as the butterfly diagram. This shows the inner cycles of reuse, repair, repurpose and remanufacture and the technical side, with the outer cycle and final process as recycling. The organic side focuses on extracting as much energy as possible, either directly through biomass or indirectly through calorie consumption, before the matter is returned to replenish the soil.

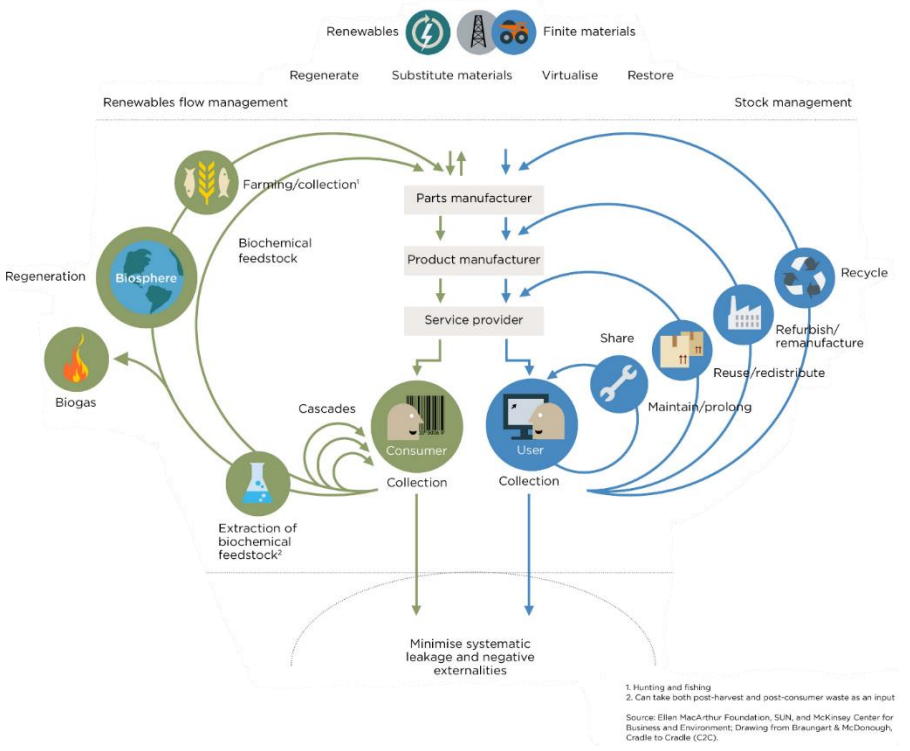

Figure 1. Circular economy butterfly diagram developed by the Ellen MacArthur Foundation (2013)

As well as working through different cyclical iterations, the circular economy works at different levels of implementation. *Micro*, at the product, company or consumer level (Elia et al., 2017; Kalmykova et al., 2018; Lewandowski, 2016), focusing on design for end of life (McDonough & Braungart, 2009) and product-as-service business models (Bressanelli et al., 2018; Spring & Araujo, 2017). *Meso* level implementation looks at eco-industrial parks like those being developed across China, where business are deliberately placed together to enable the waste from one business to be easily transferred to another that uses that waste as a resource (Mathews et al., 2018; Yuan et al., 2006). Thirdly *macro*, at national, regional or city level implementation, ensuring that the infrastructure is in place to support the effective sharing of resources and implementation of many small loops that feed into the overall circular system (Blomsma, 2018; Ellen MacArthur Foundation & ARUP, 2019; Kirchherr et al., 2017; Saidani et al., 2018).

2.1 Role of consumers

At every level of implementation and every stage of the circular economy cycles consumers play an important role. From product design consultation and uptake of subscription models of ownership, to actively seeking out second-hand goods and repairing what they own rather than throwing away, consumer involvement is vital for the success of the circular economy.

> "'Closing the loop' in the circular economy essentially requires much closer and more extended collaboration between participants. Consumers also become much more integrated because the value chain does not end at the consumption stage." (Ellen MacArthur Foundation, 2013).

Designers and engineers working in circular economy need to make sure that consumers are actively involved in each stage of the production process. For example, the purchaser could ultimately be one of many, so the resource recovery needs to be as painless for the consumer as possible (Lofthouse & Prendeville, 2018). City planners wanting to create circular urban systems must do so with the active involvement of their city's residents (Ellen MacArthur Foundation & ARUP, 2019). Not involving the people who will use the products and services being designed for them is likely to lead to costly vanity projects and products ultimately failing (Singh & Giacosa, 2019).

2.2 Barriers to adoption

Despite the importance of consumers and the public in general to the circular economy, they are one of the biggest barriers to its implementation. Research conducted by Kirchherr et al. of 208 businesses and policy-makers explores barriers to circular economy adoption in the EU and finds that "lacking consumer interest and awareness" is the most pressing issue preventing wide-scale adoption (2018). Since this research has been published there have been a few high profile circular economy media stories, such as IKEA's announcement to introduce take back schemes on their furniture (Inter IKEA Systems B.V., 2018), a focus on fast fashion (Britten, 2018; Farmer, 2020) and the business potential of circular economy (van Houten, 2019). As consumers are so vital to the success of the circular economy more needs to be done to engage them with the underlying principles of how the process should work. Preliminary research undertaken by the authors has found that often employees of companies engaged in the circular economy do not fully understand how and why their employer is engaging with the circular economy. It is prudent to point out here that, like everyone taking part in society, these employees are also consumers. To bring about this new model it is vital that we are all conscious of the roles we play, as designers and also as consumers. If we cannot take steps to become more circular in our work and daily lives, then how can we expect other people to engage.

3. Gamifying circularity

The question that needs to be asked is: how do we enable engagement with principles of the circular economy in a memorable, actionable and involving way? The authors have concluded that one of the ways to introduce ideas about the circular economy to people could be through a simple board game. Games can be important tools for educating audiences about wicked problems and are gaining more significance "as a way to bridge the communication gap between different stakeholders and support sustainability education" (Whalen et al., 2018, p. 336). They are useful devices to explain complex systems to audiences, demonstrating how different elements of these systems work together through non-linear access points that come about during gameplay, rather than linear speech. This allows audiences to come to an understanding through their own exploration instead of being told through written or verbal form. Games, "can be treated as small models of much more complex, much larger systems" (Castronova & Knowles, 2015, p. 41). Prominent game designer and theorist Jane McGonigal (2011) believes that games have the power to change by teaching ecosystems thinking, giving players the ability to think about complex ecological systems. "A good ecosystems thinker will study and learn how to anticipate the ways in which changes to one part of an ecosystem will impact other parts." (2011, pp. 297–298). Introducing ideas of circularity through a board game can provide a method to help the public understand their roles in the ecosystems necessary for successful circular economy implementation.

3.1 Serious games

A serious game is one that has a purpose beyond entertainment, their use is gaining prominence in sectors such as healthcare, education and workplace learning (Cannon-Bowers & Bowers, 2010). The majority are computer-based games, providing simulations for professionals such as firefighters or military. As they are generally designed with a specific, intended audience they are less commercially viable than video games designed solely for entertainment. They might not be practical for development in highly specialised areas, or areas where the use of computers is not permitted (Lamey & Bristow, 2015). Board games are an underused but useful avenue for the development of serious games. Serious board games offer a number of potential points over computer games: they can be developed without needing skills in programming, they can be cheap and quick to prototype, and most importantly, they involve interaction between players which can foster conversation during and after play about the subject (Castronova & Knowles, 2015; Illingworth & Wake, 2019).

3.2 Examples of serious board games

The potential for the use of serious board games is very broad reaching. For example, Bristow and Lamey (2015) developed an informal, homemade board game for use in mental health services to aid service users "in the design of their hospital environment. The advantage of a board game format is that it is familiar and unthreatening." (2015, p. 243).

This familiarity with the format allows for initial barriers to be broken down in a setting that can often be stressful and unfamiliar to patients.

To bring a serious issue to a wider audience Illingworth and Wake (2019) adapted the popular tile-based game Catan (Teuber, 1995) to introduce a global warming element as a way to generate dialogue around this complex topic.

> "Tabletop games, which offer high levels of sociability, adaptability, and tactility, create a shared space in which complex topics can be discussed and debated, and it is this capacity to foster dialogue that makes them such a productive means for discussion on the topic of global warming." (2019, p. 3).

There are a few other examples of games that tackle environmental issues. CO2 (Lacerda, 2012) is a commercial board game designed to raise awareness of the global pollution crisis. This game has been modified by Edward Castronova to explore "the difficulties that policy-makers face in dealing with the CO2 problem" (2015, p. 45). He chose CO2 as a base game as it already provided a simplification of a very complex system. By adding and removing parts of the game mechanics and adapting the rules, he was able to create a new game Climate Policy. This adaptation of the game was made using a pen and paper so can be used by anyone who owns the original game – the rules are freely available online in the International Journal of Serious Games.

Focusing on the circular economy, In the Loop Games design board games that help different groups explore areas of the circular economy specifically related to them. Katie Whalen et al. created the serious board game In the Loop to respond to the lack of understanding around complex circular economy implementation for engineering students (2015). Research had found that teaching the circular economy:

> "demands a departure from the current disciplinary and subject-focused teaching that predominates current educational paradigms, particularly in engineering education" (Whalen et al., 2018, p. 335).

The focus during gameplay is to teach students about systems thinking and material criticality through active involvement in a simulation of these systems as an addition to the traditional learning structure the students were part of. They found that "the students were able to reconnect the game to reality, think in systems, and utilize critical thinking" (2018, p. 342). The research also found that the game had implications beyond its initial intention with the potential for use with groups outside the target audience.

3.3 Serious games as boundary objects

When a game moves outside of its original intention, it becomes a boundary object. This is explained by van Pelt et al. (2015) as:

> "instruments used to facilitate the interactions between science and practice and function as the operating space between different 'social worlds' in which actors

> come together and share interpretations without the need for consensus" (2015, p. 42).

The potential for games as boundary objects when exploring complex subjects such as climate change can be investigated further when looking at the role of simulation games to bridge the boundary between climate change science and various groups. The game players do not need to have an extensive knowledge about the subject in order to understand the important concepts put forward in the game. The game play becomes a *magic circle* (Salen & Zimmerman, 2003), allowing players to experience the consequences of making different choices in the safe space of the game.

3.4 Research summary

As demonstrated in this section serious board games are an accessible way to introduce complex systems to non-expert audiences. The social dynamic allows for dialogue during and after gameplay, so players can discuss the issues around the theme of the game, potentially developing a deeper understanding of the subject. A serious game developed for a broad audience could have the potential to explain circular economy principles to different groups of people. By playing a game, audiences can experiment with a system and push the boundaries, allowing themselves to develop their own understanding of a concept.

4. Introducing 'Circul8'

This section will detail the development of a serious board game, 'Circul8', designed to explain the principles of the circular economy to a general audience. The game was initially conceived as a modification for the game Carcassonne (Wrede, 2000), a tile placing game where players can build cities, roads and farms claiming them with character tokens. The original idea was to allow players to build their towns and farms and be able to trade with one another, with a focus on the waste from one area being used by another area to create a new product. As mentioned previously, this is known as meso-level implementation (Kirchherr et al., 2017). The decision to focus on meso level implementation was taken to demonstrate the symbiotic nature of the circular economy – how one group will be reliant on another for resources. This also ties into research by one of the authors into the role of communities and networks in the circular economy.

4.1 Research and development

During the very first research and development session, the game designer trialled the game using a small selection of cards and a copy of Carcassonne (Figure 2). Trade elements were introduced through a series of cards that were selected randomly and detailed a raw material source, i.e. an oil refinery or forest, or a manufacturing base, i.e. electronics or furniture (Figure 3).

Figure 3: Initial Carcassonne gameplay

Figure 2: Carcassonne board and card modifications

The first playtest of Circul8 was held at a small doctoral conference which encouraged open and honest feedback of each workshop (CC). The feedback received followed some general questions that could be applied to any of the workshops being played but was useful. Some players mentioned aspects of game mechanics they would like to see added or improved, whereas others suggested applications for the game that had not been thought of. Table 1 shows a matrix of the initial research and development session's play testers feedback, their names are encoded for anonymity.

CCR1	The interactivity and how it can relate to policy & planning for space.	Taking the game to policy makers/planners or communities for co-design	Incorporating all elements for a circular economy - but interesting approach, could see it working	Make an online version. Keep this one too but get it online if/when people are happy with the plan/ideas
CCR2	Idea of learning about circular economy through a game with a focus on local/regional places	Influence local/regional planning in northern powerhouse	Level of complexity – making it give the message without oversimplifying	Lego pieces for resources. V. interested in how in how waste fits into cir. econ
CCR3	How the game starts with random layouts and slowly they become more intentional with players planning their next move based on potential future relationships	Making game more strategic by giving out cards before setting out tiles	How would the exchange work between cities and farms?	Money? Is the purpose to create wellbeing? How do you win?
CCR4	It's really good way of thinking where resources come [from] and how they are used. The interaction at the beginning is good as you play, and then the second part makes you think about the strategy and resources	Opportunities to modify the cards in order to give different life	How to reduce the game to not open it up that much?	Really hard work to create a game
CCR5	Great idea to gamify a quite serious subject	Game used in industry, to raise awareness of the circular economy Also, education	Making sure industry see it as serious, perceptions. It's a great idea, as a way of bridging, but for industry to	Make it digital in the future?

	How realistic to life the game can actually be	A means of understanding for private to public or environmental to private A means of knowledge exchange	understand its seriousness. You'll need to play with [it]

The research and development session introduced the two authors of this paper. Tom Cockeram is a game designer and had designed a board to be used as a base for other games. He has expertise in game mechanics and was able to take the ideas of Jessica Robins and turn them into a serious game with engaging gameplay. The following illustrates the changes the game went through to its final iteration.

Figure 4: T. Cockeram's multi-use board displaying games previously designed with school groups.

Figure 5: (on the left) First planning meeting using the pre-designed board by T. Cockeram and resource cards from the R&D session. (on the right) Development of the resource cards and gameplay logistics.

Figure 6: The green and pollution tokens, introduced as the mechanics needed to win the game.

Figure 7: Circul8 board designed and developed by T. Cockeram and J. Robins with rough draft of circular economy game elements.

4.2 Gameplay

Circul8 will focus on meso level implementation, looking at how waste streams flow in, around and out of an area. By focusing on this level of implementation the game could have a broad appeal. It doesn't use specialist terminology or concepts, simplifying the manufacture of products to 5 components: organic (plant-based materials), natural textiles (i.e. wool, cotton, leather), metals, minerals and petrochemicals. Players control a number of material processing plants and/or product manufacturing factories, they are able to choose what proportion of each they own, selecting cards randomly from a deck. Players are able to change their manufacturing factories after every turn, but they cannot change what types of material processing plants they own. The material processing plants process raw materials and also recycle or remanufacture materials once they have been used to create a product. Players earn green tokens for using second-hand materials to create their products but gain pollution tokens for creating products or making decisions about their products that are seen as detrimental to the environment, most products can be broken down into their component materials, however, some cannot and must go to landfill. The game is won overall when a player has 10 green tokens.

4.3 Methodology

Once the rules and game mechanics are finalised the game will be tested with a variety of people to gather a cross section of responses. There will be a rage of ages, including a teenage test group; testing with boardgame hobbyists, design students, and people working

in the circular economy. The players will be asked to fill out feedback forms immediately after playing and their discussions will be recorded. From the research and development session the game designers know that the game provokes a lot of conversation and that the feedback given was timely and specific, even if the questions were not. The play testers will be asked more specific questions about the game mechanics, thoughts about the systems contained within the game and overall impressions. By playtesting with a range of audiences the researchers will be able to assess what ability the game is best pitched at, and whether it is suitable for an expert and general audience. They want to be able to assess whether the messages about circular systems come across to the different groups and what changes could be made to improve the game. There is always a risk that in making something to please everyone they will create something that pleases no-one, but this is why it is important to gather a range of feedback and to be able to assess whether one or two of the test groups can be side-lined to create a wider appeal.

The intention is to make the schematics for the game and playing cards freely available so they can be printed off using a standard printer and laser cutter (or scissors, if players don't have access to a laser cutter). This way anyone will be able to play the game, regardless of finances. To keep the game as sustainable and circular as possible we will encourage players to use second-hand cardboard (from old packaging) to create their board and pieces. By keeping the game accessible to many groups the intention is to create conversations about consumption habits and how open source access could be a valuable tool in moving to a circular economy.

5. Conclusion and next steps

Through this paper we have argued for the importance of board games in disseminating ideas of circular economy. By using board games as tools, we can start to bridge the gap between a prominent model being worked towards in business and academia, and the uptake and acceptance of a new way of consuming by the public. Through the board game Circul8 we hope to develop something engaging and timely that can help audiences understand the importance of the circular economy in the fight against climate change.

The next steps for Circul8 is to be play tested with a wide variety of demographics; refining the rules and gameplay to make it accessible and enjoyable for a general audience. The authors would like to see the game printed, played and enjoyed by others, this will involve online promotion through game communities and general social media. One of the authors is looking to incorporate Circul8 into their PhD thesis, though inviting interview subjects to participate in a game with their colleagues and supply written feedback on the messages and gameplay. As the game is a microcosm of one part of the circular economy system it will be important for the authors to receive feedback from experts working within the field. This will allow the authors to assess how useful the game will be to explain circular economy concepts to a general audience.

Lastly, this paper makes a contribution to the fields of design for the circular economy, specifically design for public engagement in the circular economy, and provides another valuable example of the use of serious board games for public education. It positions Circul8 within a developing field of serious board games that focus on sustainability, and the smaller area of circular economy board games. Drawing particular attention to the importance of board games as affordable tools, their ease of creation or modification, and how they can be disseminated openly. By focusing on the circular economy as an underlying concept we have positioned the paper at an important cross-section of research: design, game theory, and sustainability.

Abstract | The article discusses the results of experimental research concerning the enhancement of waste from wheat milling. It focuses on the analysis of Mulino Marino's production system, a leader cereals' milling company in the Cuneo province (Italy). The analysis of material flows identifies wheat husks and organic sand (about 30% of total wheat grains in weight) as processing residues not classified as by-products that must be discarded as waste, following current regulations. Chemical-physical characterization certifies that they present qualities that are not optimized in their current end-of-life management. Looking at the main purposes of the circular bio-economy and the SDG12, the study focuses on defining a craft protocol for testing potential uses of company's organic waste through a set of basic experimental tests to investigate performances of wheat husks as a biopolymer, similar to thermoplastics, and as a compound for a bio-based material to replace to disposable plastics (e.g. for packaging).

KEYWORDS | ORGANIC WASTE, BIO-BASED MATERIALS, MICROBIAL PROCESSING, CRAFT-MAKING, CRADLE-TO-CRADLE

1. Introduction

Nowadays, one of the most important global challenges is to undertake tangible actions toward zero-waste production processes. The SDG 12 promotes resources and energy efficiency to ensure a better quality of life and to avoid the increasing degradation of the natural environment. The improvement of natural resources management is necessary to face the trend of increasing global population that could reach 9,7 billion people in 2050 (Department of Social and Economic Affairs, 2015). K.E. Boulding (1966) suggested that humans should move towards a "spaceman economy", considering the Earth as a single spaceship, with strict limits for extraction and pollution. An effective proposal is to move from a linear approach to the production system towards a circular or systemic one (Bonaccorso et al., 2019), increasing waste recovery and creating industrial symbiosis between complementary supply chains (Ellen McArthur Foundation, 2015).

Agriculture and food production systems present a lot of environmental issues, in terms of land use changing, soil degradation and resource depletion. It also presents critical issues in waste management like all mining processes that exploit ecosystems (Thackara, 2015). The cereals supply chain is an essential part of the food system because it is the basic diet of millions of people. In Italy, wheat cultivation is the core for the production of many basic foodstuffs. It occupies almost 1.8 million ha (Faostat, 2017) and it represents an important productive sector for the Italian economy. The Italian milling industry has more than 350 companies spread over the territory and it produces almost 7,8 million tonnes per year of wheat flour (Italmopa, 2017). On the other side, the milling industry produces also almost 3,3 million tonnes of residues not for human consumption. A part of them are used as feed in the livestock industry, but a huge amount of residues are treated as waste. In some cases, these residues present chemical-physical and mechanical properties useful for the development of bio-based materials (Genovesi & Pellizzari, 2017).

This article investigates the opportunity to enhance the milling process's residues from waste to resource for the production of new bio-based materials. The research is based on a collaboration with a company in Piedmont Region, the two residues are tested to evaluate possible applications in the design practice. The article discusses the strengths and constraints of materials obtained in terms of environmental, economic and social aspects. It also promotes the change of *mind of making* towards a systemic approach.

2. Design considering products' origin and end of life

Considering that the most environmental issues should be addressed to decisions making during the design stage (Thackara, 2005), the design culture of making products, processes and services plays an important role in promoting sustainability. Systemic Design (Bistagnino, 2011; Peruccio, 2017) proposes to adopt a systems thinking-based approach to design practice in order to reduce the ecological footprint of production processes. The

systemic approach considers products' end of life during design stages and it is inspired by nature's design principles that don't support the concept of waste (Pauli, 2015). Following the principle that “the output of a process is the resource of another one”, the concept of waste should be reconsidered. Residues obtained as results of manufacturing processes can be classified as by-products only if they respond to all requirements shown in Figure 1 (MATTM, 2017). Otherwise, they should be treated as waste. This standard is both an opportunity and a limit for alternative applications of manufacturing residues.

Figure 1. Conditions for classifying a residual substance as a by-product.

The opportunity to use them as by-products is essential to undertake tangible action towards circular supply chains. Materials and resources become strategically important in the design of production and consumption systems. Especially, the improvement of bio-based materials, composed of plant or bacterial resources, could produce a considerable effect on preventing environmental depletion. Bio-based materials are obtained by processes and technologies that allow their use in new fields of application (Genovesi & Pellizzari, 2017). Supply chains should respond to three main requirements to implement the circular approach:

1. improve the reuse of manufacturing residues looking at the “zero-waste” production;
2. promote the industrial symbiosis approach between manufacturing processes;
3. reinforce local supply chains.

The agri-food sector produces a huge amount of by-products and residues that could be used to create new valuable production processes and products (Bistagnino, 2011). Considering cereal processing inside mills, the most of residues are obtained during cleaning (mixture of dust, chaff, weed, seeds, broken and unprocessable grains) and milling processes (bran and wheat germ). The mixture of residues is not considered as by-product due to the complexity of characterization. While, bran, with high content of fibers and proteins, and wheat germ, rich in vitamins, proteins and oils, are classified as by-products suitable for human consumption and pharmaceutical usage (Grundas, 2003). Recent studies are

evaluating the opportunity to use these by-products for other applications (Kwiatkowski, 2006; Galanakis, 2018; Dietrich et al., 2018). These studies highlight by-products' properties increasing also their economic value. Significant examples can be found also in the field of products, packaging and bio-based materials, but they could present some critical aspects linked to the land-use for cultivating plants for non-food purposes. The attention should be focused on highlighting the value of agri-food waste to overtake these environmental issues.

3. Progetto Glume: from waste to resource

Progetto Glume evaluates the opportunity to test new applications of organic residues for foodservice items and food packaging that present the urgency to replace plastics from fossil resources. The concept of “Glume” refers to the leaves of graminaceous plants that protect the caryopsis until it reaches maturity and they are separated from plants and collected during the cropping and cleaning process. The study was carried out in collaboration with the “Mulino Marino”, that since 1956 is a leading milling company located in Cuneo province (Piedmont Region, Italy). The province of Cuneo is mainly characterized by agriculture and farming economy of small and medium enterprises and in 2017 cereal cultivation reached 26% of the total agricultural area under cultivation. Annually, the company produces almost 420 tons of flours and it excels in the Italian scenario for the attention to environmental sustainability and process innovation.

In the first part of the study, the Systemic Design approach, in particular the Holistic Diagnosis (Battistoni et al., 2020), was applied to analyse the company’s materials flows (raw cereal grains, by-products, final products and waste) and to identify the main critical issues linked to organic waste. While the second part focuses on lab tests to evaluate the potentials of organic residues to create alternative food service items and food packaging, following a conceptual map of testing (Figure 2).

3.1 Material flow analysis

After the grain acceptance at the mill, it undergoes some pre-cleaning processes in order to separate the non-milling parts. Foreign matter, such as weeds, straw, stones and metallic foreign elements, are collected by compressed air machinery and sieves. *Organic sand*, composed of dust, non-regular grains and vetches, is obtained as the output of other consecutive cleaning processes that are carried out on grains. Before milling, cereal grains must be brushed and filtered by a vertical peeler, following the ATEX Directive (Atmosphere Explosive, ATEX 2014/34/UE) in order to reduce the risk of explosive dusts and ashes in the milling plant. This step is compulsory to maintain high standard levels of safety inside the plant that works at high concentration of dusts and using electrical machinery which could cause the trigger. *Wheat husk* [*WH*] is obtained as residue at the end of the peeling process and it cannot be classified as a by-product following current regulations (MATTM, 2017). Unsuitable grains for milling are separated by an optical sorting machine, while the suitable

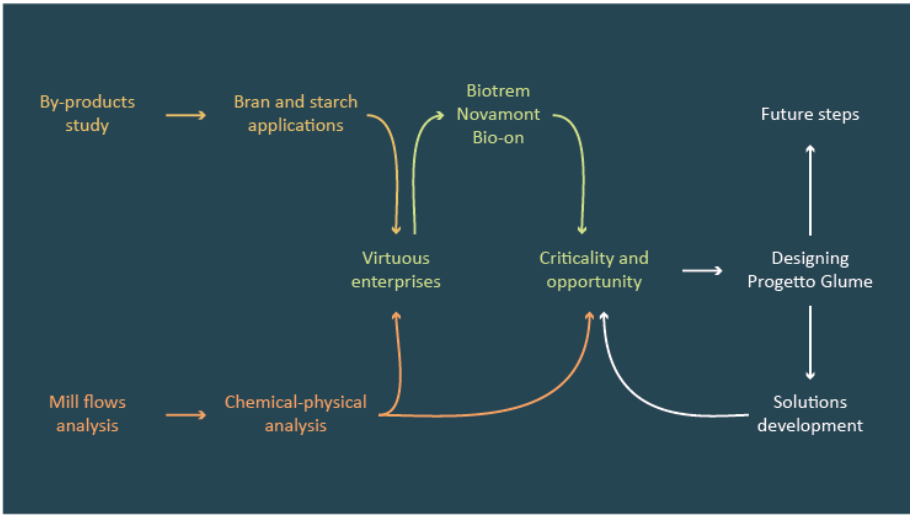

Figure 2. Design path.

part is conditioned and prepared for cylinder or stone milling. Flour, as the core product, and bran, as a by-product, are obtained at the end of the process. In 2018 the Mulino Marino has processed about 680 tons of grain obtaining 420 tons of flour. About 30% of raw cereal grain is lost as processing residues (Figure 3). Wheat flour and the first selection of bran is sold in HDPE package for human food consumption, while the other part of bran are sold as feed for the livestock industry (about 0,30 Euro/kg). On the other hand, *organic sand* and *WH* are not classified as by-products and they must be managed as organic waste, defining a critical issue for the mill. Considering the high quality of raw cereal grain processed by the mill, these residues could present properties that should be enhanced.

3.2 Qualitative analysis of organic residues

The characterization of these residues is the second step to evaluate the opportunity to reuse them for alternative uses. After processes wheat bran is stored following food management standards, minimizing risks of product contamination and alteration, while *WH* are collected in 25 kg bags and kept in an uncontrolled environment. Chemical analyses are carried out to assess their chemical composition, toxicological values, starches and protein values (data are available on request). Results assert that *WH* do not present any harmful toxicological value and they content noticeable values of proteins and fiber and about 20% of starch. The starch content is particularly important for the production of bioplastics as it is responsible for the phenomenon of gelatinisation (Lubis et al., 2018). However, the amount of starch should be increased to allow proper *WH* processing as a bio-based polymer, increasing cohesive property.

Figure 3. The analysis of raw cereal grain and output flows. Processes that generate residues: Roughing (a), Cleaning (b), Milling (c).

3.3.1 Vegetable polymer

This experiment is based on previous studies carried out by Jiang et al. (2016) and by the designer Pontus Törnqvist (The James Dyson Award, 2018). Looking at the Circular Economy and sustainability purposes, the starch used for tests, for increasing cohesive properties, is extracted exclusively from potato peels. The first step consists of the assessment of the percentages of amylose and amylopectin present in matrices of wheat and potato starch. Both of them present a range of 21-25% of amylose and 75-79% of amylopectin (Thakur et al., 2019).

The process to obtain the proper composition of the basic mixture is reached by gradually adding *WH* to a pure starch-based mixture for bio-polymer. This step is essential to assess if the addition of *WH*, as fiber, can cause adversities. Water is the solvent essential to dissolve starch crystals and moisturize *WH* fibers. The vinegar and lemon solution acts as an acid and it helps the ionization process in order to make the compound homogeneous. Glycerine gives more flexibility to the compound being a natural plasticizer. After gelatinisation, the samples are flexible and viscous, suitable for processing.

These proportions were indicated as Base Formula [*BF*], on which the following tests have been carried out to reach a Vegetable Polymer [*VP*] (Figure 4).

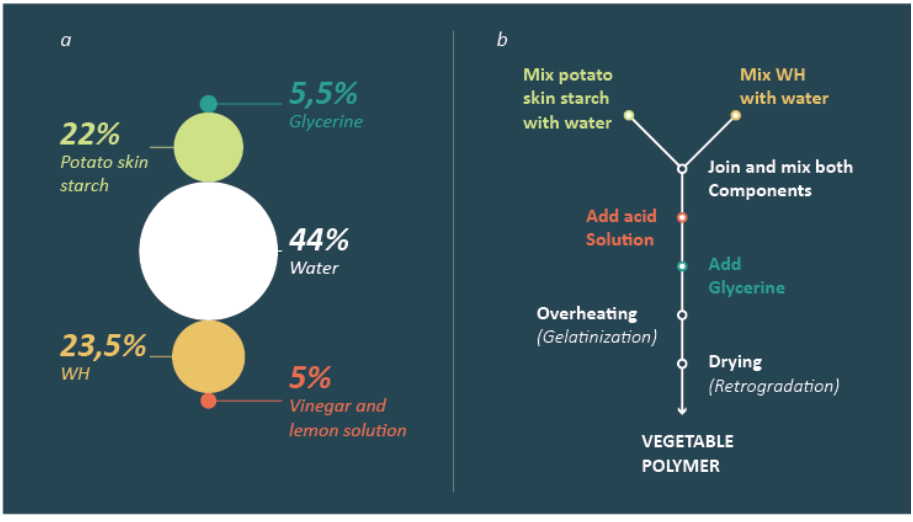

Figure 4. Optimal proportions with maximum use of WH for the basic mixture composed by WH, starch from potato skin, water, glycerine and acid solution of vinegar and lemon (a). Making processes of the Base Formula (b).

3.3.2 Manufacturing process

The BF is used to process the VP samples at room temperature, while the starch gelatinisation is done directly on the overheating phase. Preliminary tests are carried out to assess the performances of VP samples using wooden moulds under different compression times and at different drying conditions. Results of these tests are considered to improve the moulding process and the drying step.

First of all, VP samples are coated with waterproof and non-stick paper to allow a homogeneous gelatinisation process during overheating. This procedure limits the risk of dehydration of the samples surfaces exposed to contact with hot air. Furthermore, the coating avoids the adhesion of the sample surfaces to the mould surfaces during the moulding phase. The moulding process of VP sample is carried out by 3D printed moulds and counter moulds (Figure 5). Digital modelling and 3D print file generation are performed by Blender and Cura software, while printed moulds are obtained using the Anet A8 printer and Sunlu filament (PLA). Moulds shapes have sharp edges and inclined surfaces to improve the mechanical properties of VP samples.

Variables taken into account during tests concern the time of exposure to heat, the temperature reached on overheating and the drying temperatures. Drying conditions are decisive for limiting and controlling the retrogradation process of the material. *VP* samples are tested under different processing and drying conditions (Table 1).

Figure 5. Set of PLA moulds used to give shape to the vegetable polymer.

Timing	48 h	48 h	48 h	48 h	48 h	48 h

Table 1. Processing conditions test to find the basic formula.

The *BF* used to process the T5(DC) sample is taken as reference for subsequent tests, to assess which mechanical process is the most suitable for *VP* material. Base Formula has been exposed to lamination, compression at high contact temperatures and extrusion.

Simultaneously, experiments on the moulding of tableware were carried out in order to investigate the samples' deformation using different PLA mould and countermould. The texture of their internal surfaces is accentuated in order to fragment the surfaces and reduce tension during the drying phase. Mould's internal surface mesh allows the samples to lose humidity uniformly without temperature changes. Moreover, a dehydrating machine is used in order to limit retrogradation and to better control the drying process (Figure 6). Scraps obtained by pressure mouldings are collected and left to dry without specific constraints. After retrogradation, they are crushed and placed under pressure at high contact temperature (160°C), obtaining the melting of all fractions. This result highlights that *VP* samples present properties similar to thermoplastics. Furthermore, the hydration of the fragments improves the (re)gelatinisation process.

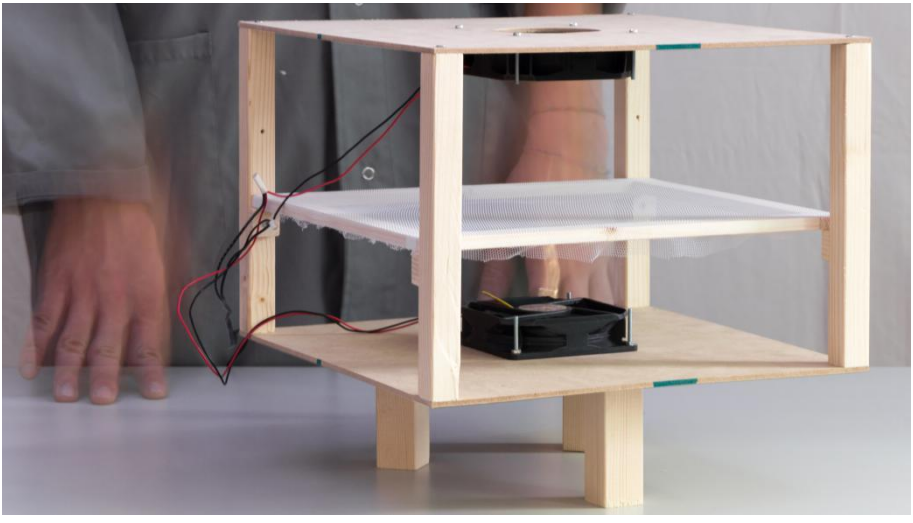

Figure 6. Self-built dehydration machine.

3.4.1 Microbial cellulose

According to From Peel to Peel project (FPTP) (Sicher, n.d.), the interaction between food-waste and microorganism can generate potential new materials. "*SCOBY*", the acronym for the Symbiotic Colony of Bacteria and Yeasts, is usually used to produce fermented foods, such as vinegar or Kombucha. This bacterial culture presents distinctive chemical-physical properties to be used as a starter to grow microbial cellulose through sugars fermentation: an extracellular polysaccharide produced by some bacterial strains such as Acetobacter,

Agrobacterium, Gluconacetobacter (Rangaswamy et al., 2015). It represents an alternative to vegetable cellulose and it is already applied in medical and food sectors. Environmental conditions of microbial cellulose growth are essential to define the final result. Parameters such as carbon source, nitrogen source, temperature, pH and type of sugars influence the generation process. The key qualities that lead to testing the *WH* potential through microbiological transformation are:

- Specific surface area;
- high water retention;
- excellent mouldability;
- tensile strength.

Tests are carried out to validate whether wheat husk could feed this bacterial culture, since *WH* is composed of starches. Moreover, *WH* contains residues of graminaceous plants and its values are similar to straw, already used in unconventional fermentation to produce bacterial nano cellulose (Corujo et al., 2016).

3.4.2 Manufacturing process

According to FPTP experiments and the results obtained by the Production of Microbial Cellulose by Tea Fungus (Shehata et al., 2007), the *WH* experiment was set up using the *SCOBY* from Fermantaholics.com and 3 tempered-glass tanks for culture growing. The percentages of elements for bacterial culture growing are calculated starting from 1 l of water (Table 2). *SCOBY* is placed into emulsion after mixing all elements. Tanks are covered with fabric to allow the respiration process and to avoid dust contamination. The temperature is set between 22-25°C.

After 3 weeks, the layers of bacterial cellulose are extracted from the emulsions. Results of the tests showed that tank 3, containing *WH* as a nutrient for bacterial culture, is the best in terms of microbial cellulose growth. The Microcial Cellulose [*MC*] layer is grown over the entire area of the emulsion and it reaches the maximum of 1.8 cm of thickness. The layer is left to dehydrate upon a grid frame to promote ventilation. Once dehydrated, mechanical tests are carried out on the *MC* to evaluate its properties. The *MC* layer is rehydrated and stretched between two transpiring surfaces in order to obtain a thin film. Both two layer's sides are clamped to prevent deformation during the second drying phase. Fans are used to maintain ventilation and to avoid mould contamination. After this step, the *MC* is pulled out from frames and it looks like a thin and tough film.

	T4(DC)	T5(DC)	T6(DC)
Wheat husk	-		5%

Water	1	1	1
Vinegar	10%	10%	10%
Sugar	5%	5%	5%
Green tea	5%	5%	-

Table 2. Percentage of the elements for bacterial culture medium.

Before dehydration, the *MC* shows excellent tensile strength and high malleability. These characteristics suggest to test it as a bio-based material for packaging. A moulding test is performed to transform the film into flour packaging. The test foresees three steps of transformation: three-dimensional forming of the film and sealing of the flaps; folding and closing of one end; fill the pack with flour and close it by sealing. Firstly, the sample is slightly hydrated and wrapped on mould; two edges are joined, folded and pressed to be welded by compression. Secondly, the bottom of the sample is made by folding and compression of the lower end. Finally, after pouring the flour, the upper ends of the sample are sealed by moisturizing the surfaces that are bent and compressed. The result is a prototype pack (Figure 7).

Figure 7. Detail of the sample manufactured by artisanal process.

Scraps of *MC* layer are hydrated to reduce their stiffness due to natural moisture loss and to make them highly malleable. Two moulds (hemisphere and truncated cone) are used as a three-dimensional shape on which the *MC* residues are manually laid and compressed. The presence of water makes the residues adhere to the moulds and single fragments blend together without being more recognizable. The detachment from the moulds does not present problems of adhesion between their surfaces and *MC* samples easily take the same shape of moulds.

4. Discussions: critical issues and positive aspects

Main issues are related to material deformations during the drying processes: water loss leads to results that are difficult to control. In the case of *VP*, samples shrink by about 1 cm and the thickness decreases from 2 to 1 mm once dried. The same phenomenon is observed for the *MC* which drastically reduces the thickness from 1.4 cm to 0.007 cm. The *VP* samples with less post-drying deformation are those processed with compression at high contact temperatures (160°C): however, this process requires high energy consumption. The drying process has a significant effect on the mechanical properties of samples. Therefore, it is necessary to perform tests in a controlled environment monitoring the below parameters:

- Air circulation;
- Temperature and pressure changes;
- Influence of external light (especially for *MC* processing).

The VP experiment shows that the temperature between 60° and 70°C is the optimal condition to promote a low viscosity fluid state. Once the 90°C threshold has been exceeded, starch processing is not possible, compromising the final result.

MC tests present the processing timing as the main critical issue, especially compared to other industrial materials. 3 weeks are necessary to obtain an area of 0.28 m² with a thickness ranging from 0.8 to 1.8 cm. Another negative issue concerns the control of acetic fermentation during MC formation: only a part of the film is cohesive and compact. Temperature changes can generate spontaneous contamination by other bacteria strains that compromise the uniformity of the surface layer. The well-formed portion of MC is generated close to the bacterial culture starter (SCOBY). Therefore, the amount and placement of SCOBY used as a starter affect the final result. Nevertheless, positive aspects are related to the possibility of generating bio-based material using a low amount of energy and without fossil-fuel components. Materials obtained don't present any physical or chemical constraints to deny their reintroduction into different production chains, nor do they contain elements harmful to the composting phases.

Positive aspects of VP processing concerns the preparation of the mixture before gelatinisation that can be carried out at room temperature (20°-25°C). VP samples reach a

volumetric detail of 1 mm thanks to compression processing, while the most performing manufacturing processes are lamination (minimum thickness reached 0.5 mm) and compression at high contact temperatures, because the sample gelatinizes and takes shape simultaneously. VP can be compared with thermoplastics because VP scraps can be easily re-processed.

Microbiological processes to obtain the MC don't require energy: the cellulose layer naturally grows on the whole surface in contact with oxygen. This process presents innovative aspects that look at the hybrid frontier of biodesign. Biodesign approach incorporates living organisms (bacteria and yeasts) into design processes as essential components (Myers, 2018). This property allows designing custom two-dimensional configurations, eliminating the production of waste from any shaping or cutting. The culture of bacteria and yeasts regenerates itself by "new" fermentation. Unlike traditional material processing, it has the ability to generate new microbial cellulose as a starter for subsequent production. MC generates two residues: solid and liquid. The solid part is composed of fermented WH that can be gelatinized following the VP procedures. While properties of the liquid fraction have not yet been characterized. These two residues are biological matrices that should be optimized.

5. Conclusion

The goal of Progetto Glume is to explore new strategies to optimize and validate the transformation of milling waste into by-products and bio-based materials through the application of an experimental approach. The study highlights many positive aspects and some constraints that should be considered as challenges for future steps. Critical issues should be taken into consideration as an opportunity for the development of *WH*'s validation tests and to define possible future scenarios. Future challenges can be organized into two main areas: the first one focuses on translating the handcraft approach to industrial one considering *VP*'s and *MC*'s mechanical performances, while the second one designing the system of local supplier (mill companies) and product processors. The research project promotes sustainable development strategies that acts locally. Indeed, future challenges include the involvement of small and medium-sized enterprises in cereals transformation sector that are able to exploit their residues reducing the environmental footprint, the exploitation of natural resources and economic costs for waste management. Project improvement should focus on design engineering, on testing *VP*'s and *MC*'s sustainability, compostability and their compliance with current regulations. The handcrafted approach adopted in the experimental research highlights that both proposals present a high potential for improvement and application in an industrial way. The abundance of locally ground cereal and the low energy requirements for waste transformation processes are the key aspects of the project. For effective development, Progetto Glume needs to create a multidisciplinary research team composed of professional figures from different fields such as biotechnology, engineering mechanics and materials science. Mill industries, feed mills

and malting plants are playing a key role in the project because they provide waste/resources for the project development. Progetto Glume is inspired by many people working in the cereal sector, agriculture and design with the aim to involve and connect people of different work and research fields. This study suggests a joint-venture of design manufacturing for sustainable and strategic development in relation to the territory and its resources.

Re-distributed manufacturing in makerspaces. Towards a model of sustainable production.

Louis Rose

Designskolen Kolding
louis.rose63@orange.fr

Abstract | This paper examines the current trends within the «making» landscape and brings forth a vision for the future evolution of the role and status of makerspaces in local communities. It does so by bringing together observations from several Danish makerspaces and the insights collected during a subsequent design experiment. This tangible, empirical and design-influenced data is contrasted and analysed throughout the process using a range of relevant literature, touching on the topics of Maker culture, distributed manufacturing, and their sustainable implications. The outcomes of this research process describe the ongoing transition taking place within the Maker movement. They also give a sense of how it is perceived from a design perspective. The paper sets out the potential that makerspaces represent in terms of local manufacturing, circular economy, and collaborative work, while highlighting the difficulties and challenges that such a vision will have to overcome in order to be achieved.

KEYWORDS | MAKERSPACE, RE-DISTRIBUTED MANUFACTURING, ENVIRONMENTAL SUSTAINABILITY, FUTURE MODEL OF PRODUCTION, DESIGN-BASED RESEARCH

1. Introduction

This paper takes its start point in the identification of a literature gap concerning productive aspects of makerspaces by Hennelly et al. (2019). They point out a “distinct lack of in-depth case study work”, as well as missing analysis of makerspaces’ “role in building local productive capacity”. Therefore, the present research, through the use of case studies and design methods, aims to contribute to the exploration of this field by investigating the possibilities that are opened up by a makerspace-based decentralized model in terms of re-distributed manufacturing.

The first makerspaces, Fablabs, demonstrated at the beginning of the 21st century the transition from virtual to physical, from bits to atoms, with the promise to allow everyone to build everything (Anderson, 2012; Gershenfeld, 2012). As they spread, the original layer of tinkering was supplemented with a layer of education and empowerment. This is now leading Fablabs to be more and more integrated within public spaces and educational institutions, as they are seen to elicit creativity and provide a culture of technology and hands-on experiments (Barrett et al., 2015).

Nevertheless, the evolution of original Fablabs also led to the emergence of other typologies of makerspaces. Hennelly et al. (2019) categorize them in three types: «Type 1 - educational and concept design; Type 2 - design and prototyping and Type 3 - prototyping and production», categories which will be used as a theoretical frame in this research.

In light of the current environmental and societal pressure, this paper premises that the conscious development of more production-centred makerspaces – above-mentioned Type 3 – could greatly disrupt our present manufacturing and consumption patterns, enabling more collaborative, reflective and sustainable behaviours (Kohtala & Hyysalo, 2015; Kostakis et al., 2016; Millard et al., 2018). The possibility presented here is that that Type 2 makerspaces will fade and make way to a bipolarization of makerspaces offer, and that the remaining poles will nurture each other in a symbiotic relationship.

These conjectures, beside taking their roots in a review of contemporary theory, are the result of an investigation consisting in two loops of Design-Based Research. The first step is based on the observation of four case studies from the region of Copenhagen, Denmark. The results from this phase were subsequently used in the elaboration of a design experiment – the second loop.

2. The case studies

The ethnographic inquiry at the base of this paper started off with the setting up of four case studies. Yin (2003) was used along this process as a framework to assess both the design and the conduct of the studies. Yin provides the current matter with an interesting definition when he writes that a case study “investigates a contemporary phenomenon within its real-

life context, especially when the boundaries between phenomenon and context are not clearly evident" (Yin, 2003, p.13). Within each case, Pink's (2015) precepts for sensory experiences of places and people also guided the initial passive understanding. More active methods, mainly semi-structured interviews, were subsequently used.

The choice of the cases was motivated by the will to collect contrasting observations to provide empirical backup to Hennelly et al.'s (2019) above mentioned classification. The Copenhagen area was targeted for its relatively wide range of makerspaces, some of them organized in emerging structured networks. Four cases and therefore four sets of observations were conducted during the time of the study.

2.1. The cases

The first case was conducted at FabLab Copenhagen. This observation holds a specific role in the study since the FabLab network has for long been communicating a clear focus on technology education, sharing and non-profit, volunteer-based business model (Massachusetts Institute of Technology, 2012). These characteristics undoubtedly place it within the scope of Type 1 makerspaces (Hennelly et al., 2019), directing its efforts towards openness, knowledge sharing, and hands-on experimentation. Therefore, it became a sort of benchmark for ensuing cases, mainly regarding the assessment of their typology.

FabLab Copenhagen's premises are certainly the first evidence of the institution's practicality, as it is hosted in former sport facilities, made available by the municipality. It therefore consists in a succession of changing rooms, repurposed as different workshops corresponding to different technologies. These latter range from desktop 3D printers to laser cutters, vinyl plotters and more traditional power and hand tools. During the observation, several people coming and going hinted at the openness and informal aspect of the place. However, one of the interviewed superusers specified that since the recent acquisition of bigger, expensive machines that the FabLab «can't afford to lose», the presence of a supervisor was required to control the access.

The second observation took place in Helsingør, at the open workshops of the recently opened Centre for Art, Design and Technology (CATCH). The makerspace is part of a cultural and leisure offer comprising a library, an exhibition hall and a food court, hosted in a mix of newly built facilities and repurposed shipyard warehouses. Beside the small 3D printers and electronic tooling found in the main building, bigger machines – CNC milling, laser cutting and power tools – as well as workbenches are available in the warehouses. The location of this makerspace as well as its short existence are plausible explanations to the very low attendance experienced there, later confirmed by an interview with the workshop manager.

The third case was conducted at Underbroen, at the heart of Copenhagen. The workshops – displaying similar technologies as in Helsingør – as well as the several working or meeting areas accessible there are placed in a succession of decreasingly sized rooms, making the most of this unique space (it is part of a bridge pier). The institution benefits from a robust

community, that was described by one of the founders as an “even mix between businesses and individuals”. This distinction is reflected in the available memberships, full-time or evening access, from which Underbroen is mainly financed. This mix of audiences was confirmed during the main observation: from the relatively large amount of people using the space that day (mainly occupied doing computer work in groups or operating the laser cutter and 3D printers), short informal interviews allowed to determine that both start-ups and non-professionals were present. A second visit on a different day gave evidence of lower attendance periods, demonstrating the difficulty to establish presence patterns (Klemichen et al., 2018)

The fourth case was organized at the Beta Factory, in the district of Sydhavn. This makerspace, hosted in large industrial facilities, features two distinct workshops with heavy-duty wood machinery. The first one comprises large wood-oriented digital tools (CNC milling, laser cutting) as well as fixed power tools, while the second offers different metal-oriented machinery. Besides that, an industrial-grade CNC sheet processing machine was being installed during the observation. Members are also provided with workbenches, material storages and dust-free areas. Despite offering the same membership plans as Underbroen, Beta Factory is much more business-oriented, both towards craftsmen and start-ups. Members, besides their own activity, also work together on collaborative projects whenever Beta Lab – the umbrella organization – receives projects requiring different skills. Different informal talks with the craftsmen highlighted the permeability between fields of competencies, as well as the exchange of skills and knowledge. A meeting gathering all the members present that day to discuss the optimization of the workshop areas confirmed the communal aspect in the management of the space (Figure 1).

Figure 1: An example of members-based decision-making at Beta Factory.

2.2. Report

The cases, selected to provide this study with contrasting data, proved to be very different examples of makerspaces. However, despite the obvious distinctions, they also showed some interesting converging trends.

The observation of the FabLab confirmed the expectations regarding Type 1 makerspaces and helped setting the benchmark standards. The openness as well as the “system D” approach were palpable. Nevertheless, it is tempting to see dynamics of expansion in the acquisition of bigger machinery. Dynamics which were interestingly also visible in Beta Factory, although in a dissimilar context.

In Helsingør bigger tooling was also observed. However, this part of the workshop really appeared under exploited, and the offer found in the main premises proved to be similar to the one at the FabLab. In addition, the overall cultural supply displayed by the CATCH and the obvious wish from the municipality to use this space as a technology-centred mediation tool makes it a good example of Type 1 makerspace. Yet it will be interesting to observe its future developments, as interviews raised evidence of a nascent networking with artists and businesses.

This business perspective is already omnipresent at Underbroen. Strong insights were provided in that sense, by the interviews with professionals as well as by the observation of a meeting held with a delegation from a big furniture company. However, these insights also revealed that what professionals found in that place is an experimental ground, at best a prototyping one, this being explained both by the location – close to other businesses – and by the limited available space. Underbroen was therefore deemed to be a Type 2.

The space constraint did not exist at Beta Factory, and the business aspect was also particularly tangible. Moreover, it displayed noteworthy dynamics in terms of internal organization, translating the FabLab’s mutual aid and sharing philosophy in a professional context. In that sense, the occasional formation of skill-based “taskforces” to answer productive challenges was also decisive in assessing Beta Factory as a developing Type 3 makerspace. Although its current activity is not so much an example of re-distributed manufacturing – most of the craftsmen are working on one-offs, for example for the event sector –, it undoubtedly displayed a great potential to one day host such local, crafts-based production.

The presented case-studies undoubtedly brought empirical evidence in favour of a makerspaces categorization such as the one proposed by Hennelly et al. (2019). Even though it has to be acknowledged that makerspaces represent an eclectic group of entities, with different focuses, approaches or social implications (Klemichen et al., 2018; Barrett, 2015; Kohtala & Hyysalo, 2015), their level of professionalization and involvement in productive activities seems to provide a convenient measure in defining overarching typologies. This classification is important since it should inform and guide the adoption of conscious

strategies and policies for the future development of makerspaces, and hopefully towards the development of a viable decentralized manufacturing network.

3. The design experiment

Capitalising on the results of the case studies, a design experiment was constructed to explore further and contrast some of the collected data. The goal was to find out significant commonalities and differences between current typologies of makerspaces, to build upon in order to envision a plausible model of decentralized, community-based production system. Designers composed the experiment panel, as it was deemed their approach could help to identify both the potential and the flaws, both the commonalities and singularities, of the exposed cases, in pragmatic and forward-looking manners (Kimbell, 2012).

The experiment was crafted on the base of two methods used in design thinking (Friis, 2016). The first one, sometimes referred to as Investigate Opposites, is a data analysis exercise aiming at comparing two radically different entities within one field or group, to explore the gap left in between and the opportunities lying there. In this case, participants were introduced to two of the aforementioned case studies, the Fablab and Beta Factory, deemed to be situated at both ends of the makerspace's spectrum – Type 1 and Type 3, from Hennelly et al.'s categorization (2019). The second method involved, Future Scenarios, is a speculating exercise where participants build on contemporary phenomena to imagine possible future evolutions for these phenomena. To ease the transition from one method to the other, the overall experiment was divided into three phases: Reaction, Confrontation and Projection. Figure 2 was produced to visually support the conduct of the workshop.

3.1. The phases

For the first phase of the experiment – Reaction –, the designers were split into two groups. Each group was assigned a case and given a time to familiarize themselves with it through a video montage of the actual space complemented with an audio record of a member from each makerspace describing the institution. An access to the websites was also granted, both to enrich the informative aspect and to inform about the communication strategies.

Then, the participants were asked to express their reactions and feelings on sticky notes that were then sorted according to four pre-established tracks: Institution, Technology, Social aspects, and Sustainability. Each track was defined using a list of keywords to make sure participants would reach equal understandings. It could be argued that the sustainability aspect is implied in the first three tracks, but it was decided to emphasize it as it has been proven to be often overlooked in similar contexts (Klemichen et al., 2018; Kohtala & Hyysalo, 2015; Millard et al., 2018).

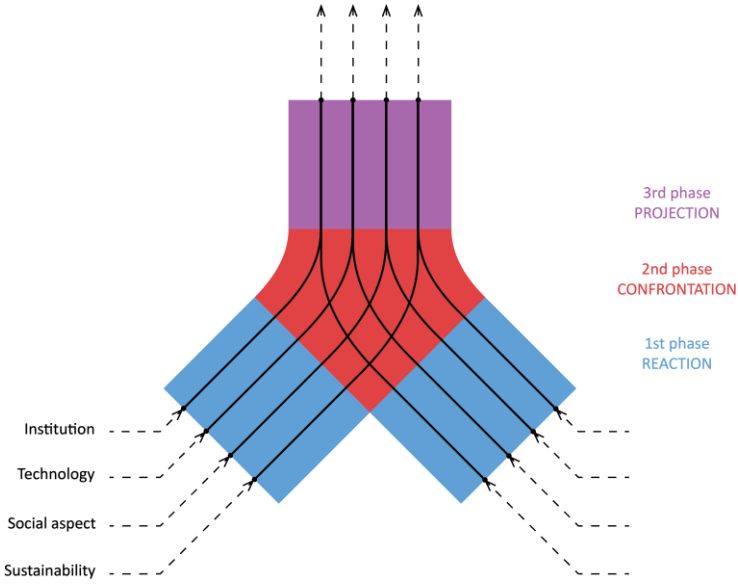

Figure 2: This graphic was showed to the participants in order to facilitate the conduct of the experiment.

For the second phase - Confrontation -, both teams gathered to briefly introduce the institutions they had been working with, before moving on to the presentation of their reactions, track by track. Along the subsequent discussion, the participants were prompted to start small debates around the different commonalities or singularities between the two models. All this second phase, as well as the third one, was audio-recorded and photographed for further analysis.

Thanks to the designers' natural propensity to envision future potential developments, the conversation was easily conducted towards building future visions for makerspaces, the goal of the third and last phase - Projection.

Participants were thorough in reading current trends in the evolution of both types of makerspaces, then translating these trends in potential future scenarios and evoking both their strengths and flaws. They even touched upon how such models could be economically sustained. Some of the points raised during this phase played an important role in the elaboration of the conjectures presented in section 4.

3.2. Report

The results of the experiment will be broken down into the four tracks given to the participants: institutions, technology, social aspects and sustainable aspects. More cross-

category analysis and discussion will take place in Section 4. (Note that from this point and until the end of the present subsection, quotations marks were used to quote contributions from the participants, either oral or written.)

The Institution track was introduced with notions such as business model, membership system, philosophy, rules or codex, etc… Within this discussion, some points were made about the «functional» and «professional» aspects of Beta Factory's set up, in opposition to the more «after-work club» look of the Fablab. If both were in turn described as «messy» and «chaotic», the aesthetic of the website and the work produced at Beta Factory were considered «design-oriented», while the free access to the Fablab and its non-commercial aspect raised questions about its business model.

Technology was the least discussed topic through the experiment, probably due to the fact that the Institution track had already absorbed some of the discussion related to the level of tooling. As for craft-related discussions, they rather took place within the Social track. In the end, beside the scale of the machinery, participants did not observe a clear difference between the two case studies. A consensus emerged around the mix of low and high tech in both spaces.

The Social track, together with the Institution, gathered most of the reactions, which could be explained by the intrinsic collaborative characteristics of both places, as well as by the human-centred approach of most designers. Observations mostly orbited around the sociality of making found in makerspaces. For Beta Factory, it was seen as the possibility for «like-minded people» to work in a «community hub» that allows them to «interact with their immediate neighbourhood». In the case of the Fablab, it is more the «focus on sharing» and more widely the social inclusion and low skill threshold which caught participants' attention.

Even though it seemed clear to the participants that sustainability was not at the heart of makerspaces preoccupations, they identified shared trends of both conscious and unconscious sustainable behaviours. The local «reuse of materials» and «sharing/donating» were among the conscious ones, while the Fablab's initiatives to build product from discarded material, and Beta Factory's shared entrepreneurial facilities were cited as unconscious sustainable features, both environmentally and socially.

4. Analysis and Discussion

From the results of the ethnographic inquiries displayed above, this section aims to identify patterns that could be further explored and harnessed in the perspective of a transition towards a productive makerspaces landscape.

Beyond the useful but static classification of the case studies, it is essential to consider the transformations at stake. In the context of this research, the main identified pattern is a bipolarization of the makerspace's spectrum.
